ABSTRACT

The objective of this study was to evaluate if Mexican Fresco cheese manufactured with specific lactic acid bacteria (LAB) presented angiotensin I-converting enzyme inhibitory (ACEI) activity. Water-soluble extracts (3 kDa) obtained from Mexican Fresco cheese prepared with specific LAB (Lactococcus, Lactobacillus, Enterococcus, and mixtures: Lactococcus-Lactobacillus and Lactococcus-Enterococcus) were evaluated for ACEI activity. Specific peptide fractions with high ACEI were analyzed using reverse phase-HPLC coupled to mass spectrometry for determination of amino acid sequence. Cheese containing Enterococcus faecium or a Lactococcus lactis ssp. lactis-Enterococcus faecium mixture showed the largest number of fractions with ACEI activity and the lowest half-maximal inhibitory concentration (IC50; <10 µg/mL). Various ACEI peptides derived from β-casein [(f(193–205), f(193–207), and f(193–209)] and αS1-casein [(f(1–15), f(1–22), f(14–23), and f(24–34)] were found. The Mexican Fresco cheese manufactured with specific LAB strains produced peptides with potential antihypertensive activity.

Key words: bioactive peptide, lactic acid bacteria, Mexican Fresco cheese

INTRODUCTION

Hypertension is a worldwide risk factor for cardiovascular disease and stroke (Whitworth, 2005). It is now accepted that peptides released by enzymatic hydrolysis of food proteins may exhibit antihypertensive activity by inhibiting the angiotensin-converting enzyme (ACE; FitzGerald and Meisel, 2000; Seppo et al., 2003). Angiotensin-converting enzyme (peptidyl-di-peptide hydrolase, EC 3.4.15.1) is an exopeptidase that cleaves dipeptides from the C-terminal side of various oligopeptides. As part of the renin-angiotensin system, ACE hydrolyses angiotensin I, an inactive decapeptide, to the potent vasoconstrictor angiotensin II. It also inactivates the vasodilator bradykinin, which is involved in blood pressure control (Korhonen and Pihlanto, 2006; Lopez-Fandiño et al., 2006). Remarkable efforts have been made in the production of natural foods for the promotion of a healthier lifestyle, with emphasis in the role played by the diet in disease prevention and treatment. These components include food-derived bioactive peptides and, more specifically, peptides with ACE inhibitory (ACEI) activity. Among them, milk proteins are identified as one of the most important sources of ACE inhibitors.

Cheese is an important dairy product containing numerous peptides released by proteolysis during the ripening period. The profile of these peptides differs depending on the variety of cheese and ripening time (Gómez-Ruiz et al., 2006). These peptides participate in the flavor and texture of cheese (Gómez-Ruiz et al., 2007), but some of them have also revealed ACEI activity (Saito et al., 2000; Silva et al., 2006; Bütköfer et al., 2008). However, those studies were conducted with ripened cheeses. To the best of our knowledge, the ACEI activity of unripened cheeses such as Mexican Fresco cheese has not been reported.

Mexican Fresco cheese is characterized by being high in moisture content, having a mild milky flavor, a soft and creamy texture, and a very short shelf-life (Van Hekken and Farkye, 2003; Torres-Llanez et al., 2006). This type of cheese has a moisture content of 63.4 ± 3.8%, a protein content of 15.63 ± 1.35%, a fat content of 15 ± 3.16%, and a pH of 6.0 ± 0.2 (Torres-Llanez et al., 2006). This rennet-set cheese is the most popular cheese consumed in Mexico and is a preferred choice of Mexican residents in the United States. Consequently, it would be valuable to know if this type of cheese presented ACEI activity so that it could potentially offer an additional food value. Thus, the aim of this study was to evaluate if Mexican Fresco cheese made with specific lactic acid bacteria (LAB) presented ACEI activity and to find and characterize peptides with ACEI activity.
**MATERIALS AND METHODS**

**LAB Strains and Culture Propagation**

Strains of LAB used in the manufacture of Mexican Fresco cheese were obtained from the Dairy Laboratory collection at Centro de Investigación en Alimentación y Desarrollo (CIAD, Hermosillo, Sonora, Mexico). Cultures consisted of 3 strains: *Lactococcus lactis* ssp. *lactis*, *Enterococcus faecium*, and *Lactobacillus casei* ssp. *lactis* – *Lb. casei* and *Lc. lactis* mixtures of LAB strains and culture propagation.

**Cheesemaking Procedures**

Two batches of raw milk (60 L) collected on 2 occasions from a local dairy farm were used for cheese manufacture. Milk was pasteurized at 65°C for 30 min, and then set at 34°C for culture inoculation. Five cheeses were manufactured with different LAB cultures (*Lc. lactis* ssp. *lactis*, *E. faecium*, *Lb. casei*, and *Lc. lactis* ssp. *lactis* – *Lb. casei* and *Lc. lactis* – *E. faecium*) at inoculum levels of 1 mL/L for single strains and 0.5 mL/L for mixed strains. Additionally, one control cheese was manufactured without added LAB. After a 2-h incubation, 1.5 mL of commercial calf rennet (strength 1:10,000, Industrias Cuamex, S.A. de C.V., Mexico, D. F., Mexico) was added to each milk batch. Coagulation took place at 32 to 34°C for 1 h. Then, the curd was cut until a grain the size of a hazelnut was obtained. At this stage, whey was drained off and salt was added (3%) to the curd, which was manually homogenized. Finally, the salted curd was molded and stored overnight under refrigeration (4°C). Under these procedures, 5 experimental Mexican Fresco cheeses from each milk batch were prepared: *Lc. lactis* ssp. *lactis* (CLI), *E. faecium* (CEf), *Lb. casei* (CLC), *Lc. lactis* ssp. *lactis* – *Lb. casei* (CLLC), and *Lc. lactis* ssp. *lactis* – *E. faecium* (CLIEf). Water-soluble cheese extracts were prepared 5 d after cheese storage at 4°C. Sampling at d 5 was selected because this type of cheese is consummed immediately after manufacture and not later than 1 wk after manufacture.

**Preparation of Water-Soluble Extracts**

Five-day-old cheese samples (20 g) were homogenized in 40 mL of deionized water during 5 min using a Stomacher 400 (Colworth, London, UK). The resulting homogenates were held at 4°C for 1 h. The insoluble material was then separated by centrifugation at 10,000 × g for 30 min (model RC5C, Sorval Wilmington, NC) at 4°C. The supernatants were filtered through glass wool to remove residual suspended fat and freeze-dried.

Lyophilized water-soluble extracts (WSE) were redissolved in deionized water (10%), filtered with macrosep centrifugal devices (Pall Life Science, Ann Arbor, MI) with a cut-off point of 3,000 Da, and centrifuged at 3,000 × g for 45 min at 25°C.

The concentration of protein in WSE was determined by the Bradford method (Bio-Rad Protein Assay; http://www.bio-rad.com/LifeScience/pdf/Bulletin_9004.pdf; Gobbetti et al., 2000; Donkor et al., 2007). Briefly, 800 μL from each reconstituted WSE was placed in a clean and dry test tube; then, 200 μL of dye reagent was added to each tube and vortexed. The test tubes were incubated at room temperature (25°C) for at least 5 min. After that, absorbance was measured at 595 nm. All analyses were performed in duplicate.

**WSE Analysis by Reverse Phase HPLC**

Reverse phase (RP)-HPLC was performed by using an Agilent 1100 Series HPLC (Agilent Technologies, Waldbronn, Germany). Reconstituted WSE (20 μL) were injected into the reverse-phase column (300 Extend-C18, 4.6 mm × 250 mm, 5 μm; Agilent Technologies, Santa Clara, CA). Separation was conducted at room temperature (~22°C) at a flow rate of 0.5 mL/min. Solvent A was a mixture of water:trifluoroacetic acid (1,000:0.1, vol/vol) and solvent B consisted of acetonitrile:trifluoroacetic acid (1,000:0.1, vol/vol). Peptides were eluted by using a linear gradient of solvent B in A, from 5 to 100% in 77 min. The concentration of solvent B was linearly increased from 0 to 5% for 16 min; from 5 to 46% between 16 and 62 min; and from 46 to 100% between 62 and 72 min, finally reaching 100% between 72 and 77 min. Absorbance was recorded at 214 nm.

Sixteen fractions from each WSE were collected using a fraction collector (Agilent 1100 Series, Analytical FC, Waldbronn, Germany). Fractions from several chromatographic runs were pooled and dried using a Centrivap Concentrator (Labconco, Kansas City, MO). Then, fractions were redissolved in 300 μL of borate buffer (100 mM, pH 8.3) containing 300 mM NaCl. Aliquots (100 μL) from each fraction were used to determine ACEI activity. Protein content of each fraction was estimated by the Bradford assay as described previously.

**Determination of ACEI Activity**

Activity of ACEI was determined following the spectrophotometric assay reported by Nakamura et
RESULTS AND DISCUSSION

ACEI Activities of Mexican Fresco Cheeses

Water-soluble extracts (<3 kDa) obtained from Mexican Fresco cheeses inoculated with LAB showed ACEI activities ranging between 95.3 and 99.8% and IC$_{50}$ values ranging between 5.2 and 10.7 μg/mL (Table 1). These results suggested that ACEI activity and IC$_{50}$ in cheese WSE were dependent on the specific LAB used for cheese manufacture. It has been reported that LAB could generate a large variety of peptides, including bioactive peptides. In fact, ACE inhibitory peptides have been found in several types of aged cheeses, which differed with respect to the type of starter and the ripening conditions used (Saito et al., 2000; Sieber et al., 2009).

The highest ACEI activity corresponded to the WSE from cheese made with the Lc. lactis spp. lactis-Lb. casei mixture. However, the lowest IC$_{50}$ was obtained for the WSE from cheese made with Lc. lactis spp. lactis (Table 1). The potency of an ACE inhibitor is usually expressed as an IC$_{50}$ value, which is the concentration of inhibitor leading to 50% inhibition of ACE activity (Heber et al., 2010). Thus, a cheese extract with the lowest IC$_{50}$ requires a lower concentration of peptide to achieve ACE inhibition. It is interesting to notice that Lc. lactis spp. lactis was the prevalent species in artisanal Mexican Fresco cheese produced from raw milk (Torres-Llanez et al., 2006). Thus, it would be expected that this type of cheese might have significant ACEI activity.

The release of ACE-inhibitory peptides in Cheddar cheese made with lactococci and probiotic strains of Lb. casei has been reported (Ong et al., 2007; Ong and Shah, 2008), although their results suggested that ACEI activity was dependent on proteolysis during ripening. On the other hand, ACEI activity in Mexican Fresco cheese determined in this study was detected only 5 d after manufacture. It has been reported that ACEI ac-
Antihypertensive potential of Mexican Fresco cheese: activity produced in milk after a 48-h incubation with Lc. lactis isolated from different niches is strain-dependent (Rodriguez-Figueroa et al., 2010). In that report, the highest ACEI activities were found in WSE from milk inoculated with wild Lc. lactis strains isolated from artisanal dairy products. In fact, a strain isolated from an artisanal Mexican cheese presented the lowest IC\textsubscript{50} (13 μg/mL) of all fermented milks (Rodriguez-Figueroa et al., 2010).

**Peptide Isolation and Collection by HPLC**

Semi-preparative RP-HPLC of WSE resulted in 14 to 16 fractions collected for each cheese. The ACEI activity and the corresponding IC\textsubscript{50} values for WSE fractions from Mexican Fresco cheese made with Lc. lactis, Lb. casei, or E. faecium are shown in Figure 1.

From the 14 collected fractions (F1 to F14) of the WSE from cheese made with Lc. lactis (Figure 1A), only 7 fractions presented ACEI activity. The IC\textsubscript{50} values of these fractions were much lower than the IC\textsubscript{50} of 500 or 520 μg/mL obtained for milk fermented by Lc. lactis ssp. lactis (Pihlanto et al., 2010) or Lc. lactis ssp. cremoris (Muguerza et al., 2006), respectively. In fact, fractions F1, F11, and F12 presented IC\textsubscript{50} values <10 μg/mL (Figure 1A).

From the 14 collected fractions (F1 to F14) of the WSE from cheese made with Lb. casei (Figure 1B), only 8 fractions presented ACEI activity. In this case, all fractions except F3, F7, and F10 presented IC\textsubscript{50} values <10 μg/mL. The inclusion of Lb. casei as a probiotic adjunct in Cheddar cheeses resulted in WSE with increased ACEI activity, with IC\textsubscript{50} ranging from 0.1 to 2.0 mg/mL (Ong et al., 2007). However, the Lb. casei strain used in the present study appeared to have a more pronounced ACE inhibition because IC\textsubscript{50} values for the different fractions (Figure 1B) and the WSE extract (5.3 ± 0.1, Table 1) were much lower than IC\textsubscript{50} values reported for Cheddar cheeses (Ong et al., 2007).

From the 15 collected fractions (F1 to F15) of the WSE from cheese made with E. faecium (Figure 1C), F1 to F12 showed ACEI activity and IC\textsubscript{50} values <6 μg/mL (Figure 1C). In particular, F3 exhibited an IC\textsubscript{50} value of 2.6 μg/mL (Figure 1C). Similar IC\textsubscript{50} values were reported for fractions produced by proteases from Cynara cardunculus in cheese-like systems (Silva et al., 2006), although the IC\textsubscript{50} values obtained in the present study were much lower than the IC\textsubscript{50} values of 34 to 59 μg/mL obtained for milk fermented by E. faecalis (Muguerza et al., 2006; Quirós et al., 2007). Interestingly, E. faecalis has been detected in artisanal Mexican Fresco cheese manufactured from raw milk (Torres-Llanez et al., 2006) and was further confirmed by others (Renye et al., 2008).

The ACEI activity and their corresponding IC\textsubscript{50} values presented in WSE from Mexican Fresco cheese made with the Lc. lactis ssp. lactis–Lb. casei mixture are shown in Figure 2A. Although only 5 fractions showed ACEI activity, IC\textsubscript{50} values were all <10 μg/mL (Figure 2A). On the other hand, cheese made with the Lc. lactis ssp. lactis–E. faecium mixture presented a larger number of fractions (13) with ACEI activity and IC\textsubscript{50} values <10 μg/mL, except for F3 (Figure 2B).

From these results, it appears that Mexican Fresco cheese manufactured from milk inoculated with E. faecium or Lc. lactis ssp. lactis–E. faecium mixture showed a negative inhibition; in fact, negative mutants for peptidase activities presented higher ACEI activities than their wildtype counterparts (Algaron et al., 2004). Thus, differences among ACEI activities from WSE of cheeses made with...
specific LAB may be due to differences in the proteinaises and peptidases of the specific LAB present. Thus, addition of these specific LAB strains to milk for Fresco cheese manufacture may be a good alternative for increasing ACE inhibition and could add value to this type of traditional Mexican cheese. Indeed, *E. faecium* and *Lc. lactis* were the most abundant LAB species detected in Mexican Fresco cheese manufactured from raw milk (Torres-Llanez et al., 2006).

Identification of Peptides by LC-ESI-MS/MS

Even though, the initial number of collected fractions was very high (73 fractions), many fractions did not produce an adequate signal for MS detection. Therefore, only 4 fractions from cheese made with *E. faecium* and 1 fraction from cheese made with *Lb. casei* were further analyzed by LC-ESI-MS/MS. A typical mass spectrum for one of the fractions (F10) from cheese made with *E. faecium* showing double-charge ions, 941.7 and 729.9, is depicted in Figures 3A and 3B. The tandem mass spectrum of these 2 double-charge ions and the amino acid sequences of these peptides are shown in Figure 3C and 3D. Fraction F10 contained 2 peptides with YQEPVLGPVRGPF (f193–205) and YQEPVLGPVRGPFPIIV (f193–209) sequences from β-CN.

Observed and calculated masses, molecular ions (m/z), protein fragments, and amino acid sequences for the identified peptides are shown in Table 2. Peptide sequences in Mexican Fresco cheese made with *E. faecium* or *Lb. casei* were identified as α_{S1} and β-CN fragments and their size varied from 10 to 22 amino acid residues. Peptides (<3 kDa) belonging to κ-casein were not identified in any of the cheeses. The high proteolysis resistance of para-κ-CN in cheese may explain this finding (Swaisgood, 2003).

In this study, 4 peptides were identified as deriving from the N-terminal portion of α_{S1}-CN and 3 peptides as deriving from the C-terminal of β-CN (Table 2). All identified peptides in this study had a strong hydrophobic character and all except one were rich in the amino acid proline. In addition, these peptides contained arginine and lysine in the C-terminal portion. According to the literature, this portion corresponded to the hydrophobic portion of α_{S1} and β-CN (Swaisgood, 2003). Activity of ACEI is strongly influenced by the C-terminal tripeptide sequence in the substrate; competitive inhibitors or substrates containing hydrophobic (aromatic or branched side chains) amino acid residues at each of the C-terminal positions appear to be preferred by ACE (Lopez-Fandiño et al., 2006). Another characteristic of these bioactive peptides is the presence of the positive charge on the guanidine and the ε-amino group of the C-terminal arginine and the lysine side chain, respectively, which contribute substantially to the potency of inhibition (Gobbetti et al., 2004; Lopez-Fandiño et al., 2006). Additionally, the presence of proline in the C-terminal sequence contributes to the correct location of the peptide in the active site of the enzyme, probably because of the rigid structure of this residue (Cushman et al., 1977).

Various peptides with ACEI activity that originated from the N-terminal portions of α_{S1}-CN were also reported in aged cheeses such as Gouda (Saito et al., 2000) and Cheddar cheese (Ong et al., 2007) or in cheese-like systems prepared with proteases from *Cynara cardunculus* (Silva et al., 2006). Moreover, a peptide from the C-terminal portion of β-CN with ACEI activity, YQEPVLGPVRGPFPIIV (f193–209), was reported in Manchego cheese (Gómez-Ruiz et al., 2002). Other studies also reported this peptide in Cheddar cheese (Ong et al., 2007); moreover, this peptide was likely the hydrolysis product of chymosin and cell wall-associated proteinasies from starter lactococci or from probiotic adjuncts (Ong et al., 2007). On the contrary, peptide EVLNENLLRF (α_{S1}-CN, f14–23) found in the present study was not reported in previous studies. Proteinasies of LAB can hydrolyze more than 40% of the peptide bonds of α_{S1} and β-CN, resulting in the formation of more than 100 different oligopeptides, which are in turn actively degraded by the complex peptidase system (Ong et al., 2007). Consequently, different LAB could generate a wide variety of peptides.

CONCLUSIONS

Although Mexican Fresco cheese is unripened, the addition of specific strains of LAB during cheese manufacture resulted in the production of ACE inhibitors. From the cheeses studied, those containing E. faecium or a Lc. lactis ssp. lactis–E. faecium mixture produced the most peptide fractions with ACEI activity. Thus, Mexican Fresco cheese manufactured with specific LAB strains produced peptides with potential health benefits; these benefits need to be tested by conducting in vivo studies.
