ABSTRACT

Lung cancers are among the most common cancers in the world, and the search for effective and safe drugs for the chemoprevention and therapy of pulmonary cancer has become important. In this study, bovine lactoferrin (bLF) was used in both in vitro and in vivo approaches to investigate its activity against lung cancer. A human lung cancer cell line, A549, which expresses a high level of vascular endothelial growth factor (VEGF) under hypoxia, was used as an in vitro system for bLF treatment. A strain of transgenic mice carrying the human VEGF-A165 (hVEGF-A165) gene, which induces pulmonary tumors, was used as an in vivo lung cancer therapy model. We found that bLF significantly decreased proliferation of A549 cells by decreasing the expression of VEGF protein in a dose-dependent manner. Furthermore, oral administration of bLF at 300 mg/kg of body weight 3 times a week for 1.5 mo to the transgenic mice overexpressing hVEGF-A165 significantly eliminated expression of hVEGF-A165 and suppressed the formation of tumors. Additionally, treatment with bLF significantly decreased the levels of proinflammatory cytokines, such as tumor necrosis factor-α, and antiinflammatory cytokines, such as IL-4 and IL-10. Levels of IL-6, which is both a proinflammatory and antiinflammatory cytokine, were also reduced. Treatment with bLF decreased levels of tumor necrosis factor-α, IL-4, IL-6, and IL-10 cytokines, resulting in limited inflammation, which then restricted growth of the lung cancer. Our results revealed that bLF is an inhibitor of angiogenesis and blocks lung cell inflammation; as such, it has considerable potential for therapeutic use in the treatment of lung cancer.

Key words: bovine lactoferrin, pulmonary cancer, vascular endothelial growth factor (VEGF), transgenic mice

INTRODUCTION

For several decades, lung cancer has been the most common cancer worldwide (Li et al., 2010). Most new cases of lung cancer now occur in developing countries (55%) and it is still the most common type of cancer in men (1.1 million cases, 16.5% of the total), with high rates in central, eastern, and southern Europe, North America, and East Asia (Ferlay et al., 2010). Although the treatment of lung cancer has improved, the mortality rate of lung cancer patients remains high. To reduce these high rates of mortality, many researchers have focused on methods for tumor prevention in addition to more effective treatments (Lin et al., 2009). Recently, researchers have found natural food components or products of digestion that could mediate the process of angiogenesis and metastasis (Singh et al., 2006; Yang and Wang, 2010). Researchers have shown the anticancer potential of dietary proteins, peptides, and amino acids, which may be natural products of fermentation and enzymatic hydrolysis or products of gastrointestinal digestion (de Mejia and Dia, 2010). These compounds mediate apoptosis and angiogenesis, which are vital steps in controlling tumor metastasis.

Bovine lactoferrin (bLF), a siderophilic protein with 2 iron-binding sites, has a wide range of biological activities, including anticancer effects, antimicrobial effects, and improvement of immunomodulatory functions (de Mejia and Dia, 2010). Chemopreventive and cell growth inhibitory activities of bLF have been demonstrated in esophageal (Ushida et al., 1999), lung (Li et al., 2011), colon (Tsuda et al., 1998), bladder (Masuda et al., 2000), mammary (Yamada et al., 2008; Duarte et al., 2011), stomach (Xu et al., 2010), and tongue (Tanaka et al., 2000) cancers. The anticancer functions of bLF are thought to be exerted through its innate
ability to bind iron (González-Chávez et al., 2009). The iron could accelerate oxidation, thereby disrupting nucleic acid structure. Other potential mechanisms of anticancer functions include induction of programmed cell death and regulation of cell cycle protein expression (Lönnerald and Iyer, 1995; Rodrigues et al., 2009). However, the antiangiogenesis effects of bLF during tumor growth are poorly understood.

In the early stages of cancer, the unregulated proliferation of cancer cells leads to a deficiency of both nutrients and oxygen, causing significant cell death. Cell death triggers an inflammatory response, activates hypoxia-inducible factor 1α (HIF-1α), promotes the expression of the vascular endothelial growth factor (VEGF)-A mRNA, and causes angiogenesis. Of the VEGF family, VEGF-A is the one of most interest in human medicine for specialists and medical teams. Four isoforms of VEGF-A are known, including VEGF-A121, VEGF-A165, VEGF-A189, and VEGF-A206; VEGF-A165, the common type, primarily functions to promote angiogenesis. Secreted VEGF-A165 binds to the receptor VEGFR2 and activates a downstream signal that induces vasculogenesis (Ferrara, 2002). When cancer cells secrete a large amount of VEGF-A165, vasculogenesis is induced to provide sufficient nutrients and oxygen to the tumor, thus increasing the tumor growth rate. Expression of VEGF-A165 is positively related to the growth and spread of cancer cells (Coussens and Werb, 2002). Therefore, the development of medicines that target VEGF-A165 is an important topic of study.

In this study, we used both in vitro and in vivo approaches to investigate the effects of VEGF expression in lung cancers treated with bLF, which was purified from bovine milk. Human lung cancer cells and an animal model of human (h)VEGF-A165-induced lung tumor transgenic mice were applied to examine the protection mechanisms of bLF on human and mouse lung carcinomas.

**MATERIALS AND METHODS**

**Cell Culture**

Human lung adenocarcinoma cell lines A549 [American Type Culture Collection (ATCC), Manassas, VA; cat. no. CCL-185] and CL1–0 (provided by J. J. W. Chen, Institute of Biomedical Science, National Chung Hsing University, Taichung, Taiwan; Chen et al., 2001) and the human bronchial epithelial cell line Beas 2B (ATCC; cat. no. CRL-9609) were cultured in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 10% fetal bovine serum (FBS). Cells were incubated in a 5% CO₂ incubator at 37°C (Chen et al., 2008c).

**Cell Viability Assay**

To measure the cytotoxicity of bLF (Sigma-Aldrich, St. Louis, MO) on cell proliferation, A549, CL1–0, and Beas 2B cells (2 × 10⁵ cells/well) were seeded into a 96-well plate in triplicate and incubated for 3 h to allow cell adherence. First, 200 μL of fresh medium containing various concentrations of bLF (15 to 0.9375 mg/mL) or H₂O (control) was added into the cultures and incubated at 37°C for 48 h. Following the removal of the medium from the wells, 100 μL of tetrazolium salt solution [1 mL of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) in 10 mL of DMEM] was added. After 4 h of incubation at 37°C, the medium was removed and 100 μL of dimethyl sulfoxide (DMSO) was added to dissolve the formazan crystals. Absorbance was measured in an ELISA reader at 570 nm (Yen et al., 2009). The cell viability ratio (%) was calculated as follows: % viability = (absorbance of test sample/absorbance of control) × 100%.

**Growth Curve and Doubling Time**

The A549 cell line was used to generate a growth curve using a 24-well microtiter plate. A seeding density of 1,500 cells in a 1-mL volume of DMEM supplemented with 10% FBS was used per well. Growing cultures were trypsinized at d 1, 4, 7, 8, 9, and 10, and the number of live cells per well was determined in triplicate (Chen et al., 2010). The doubling time (in hours) was calculated as h × ln(2)/ln(c2/c1), where c1 and c2 are the cell concentrations at the beginning and the end of the chosen period of time.

**Reverse-Transcription PCR Analysis**

The A549 cells were seeded in a 10-cm dish at 5 × 10⁶ cells/well. After 2 d, 10 mL of DMEM supplemented with 10% FBS or 0.1% FBS and containing various concentrations of bLF (100, 50, 25, 12.5, and 6.25 mg per 10-cm dish) was added to the cultures and incubated at 37°C for 48 h. The reverse-transcription PCR (RT-PCR) protocol was described previously (Hung et al., 2010; Tsai et al., 2010). Primers for vegf were 5'-CAGAAGCAG AATGTGACCATC-3' (sense) and 5'-CTTCTGCGATGTCATGAGC-3' (antisense). β-Actin was used as an internal control with the following primers: 5'-CCGTCTTCCCCTC-CATCGTGG-3' (sense) and 5'-CGCAGTCTATG TGAAG GTGTTG-3' (antisense). The amplified RT-PCR products were analyzed with 2% agarose gel electrophoresis containing ethidium bromide (Tung et al., 2011).
**Western Blotting**

Cells were homogenized in 300 μL of RIPA (radioimmunoprecipitation assay) buffer [5 mM Tris-HCl, pH 7.4, 0.15 M NaCl, 1% Nonidet P40, 0.25% sodium deoxycholate, 5 mM EDTA, and 1 mM ethylene glycol-bis(2- aminoethyl-ether)-N,N,N’,N’-tetraacetic acid, EGTA; Chen et al., 2008c] and the homogenates were centrifuged at 12,000 × g for 30 min at 4°C. Protein (40 μg) was then separated by 10% SDS-PAGE and electrotransferred to polyvinyl difluoride membranes. The membranes were incubated in blocking solution for 2 h and then incubated with primary antibody (anti-VEGF-A or anti-GAPDH) overnight at 4°C. After washing, the membranes were incubated with a goat anti-rabbit IgG peroxidase-conjugated secondary antibody directed against the primary antibody. The membranes were developed using an enhanced chemiluminescence Western blot detection system (Chen et al., 2008a).

**Homozygous Transgenic Mouse Production**

The mccsp-hVegf-A165-sv40poly(A) transgenic mice were generated by pronuclear microinjection (Tung et al., 2011). To detect the hVEGF-A165 transgene in the transgenic mice with a homozygous (hVEGF-A165+/+) or heterozygous (hVEGF-A165+/−) genotype, the mice were analyzed by RT-PCR of lung tissue mRNA with the primer set of VEGF-94(+):

```
5′-AAGGAGGAGGGCAGAATCATC-3′
```

and VEGF-315(−):

```
5′-GAGGTTTGATCCGATAATCTG-3′
```

The exogenous human VEGF-A165 protein expression levels in homozygous (hVEGF-A165+/+) or heterozygous (hVEGF-A165+/−) transgenic mice were also detected by Western blot as described above.

**Animal Trials**

The transgenic mice were given a standard laboratory diet and distilled water ad libitum and kept on a 12-h light/dark cycle at 22 ± 2°C. This animal study was approved by the Institutional Animal Care and Utilization Committee of National Chung Hsing University. The transgenic mice with the homozygous (hVEGF-A165+/+) genotype were randomly assigned into 2 groups for treatment (n = 6): (1) transgenic mice treated with PBS as mock control (Tg/Mock) and (2) transgenic mice treated with bLF (Tg/bLF) groups. After oral administration of bLF at 300 mg/kg of BW 3 times a week, mice were killed at 10.5 mo of age, following 1.5 mo of bLF administration. Lung tissues were collected for pathological histology, immunohistochemistry staining, and RNA and protein extractions. All experiments were repeated twice.

**Histopathology Examination**

Lung tissue was fixed in 10% buffered formaldehyde (pH 7.0), embedded with paraffin, sectioned into 3-μm sections, and examined using hematoxylin and eosin (H&E) staining (Chen et al., 2008b). Scores of lung histopathology were examined by 2 independent pathologists.

**Immunohistochemistry Staining**

Formaldehyde-fixed and paraffin-embedded sections were prepared accordingly (Hung et al., 2010). The sections were incubated in 3% hydrogen peroxide for 10 min to block endogenous peroxidase activity and then incubated overnight at 4°C with primary rabbit monoclonal antibody against hVEGF-A using a 1:40 working dilution. For antigen retrieval, the sections were immunostained with the Vectastain ABC kit (Universal, Vector Laboratories Inc., Burlingame, CA) as described previously (Tung et al., 2011). Diaminobenzidine (DAB) was used for staining development, and the sections were counterstained with hematoxylin (Liu et al., 2008). The negative control consisted of substituting normal serum for the primary antibody.

**Real-Time RT-PCR**

Real-time RT-PCR was performed using Rotor-Gene SYBR Green kit (Corbett Research, Mortlake, New South Wales, Australia). To evaluate gene expression, real-time RT-PCR was performed on 3 genes: vegf, IL-6, and tumor necrosis factor-α (TNF-α) using cDNA from lung tissues; β-actin was used as an internal control (Chen et al., 2003).

**ELISA for Cytokines**

Blood samples were collected and centrifuged at 1,400 × g at 4°C for 15 min, and concentrations of VEGF, TNF-α, IL-4, IL-6, and IL-10 in serum supernatants were determined using the commercial kits from PeproTech Inc. (Rocky Hill, NJ; Chen et al., 2010).

**Statistical Analysis**

Data were presented as means ± standard error (SE) or means ± standard deviations (SD). The data in Figure 1 and Figure 2 were calculated by Scheffé’s test and values <0.05 were considered to be significant.
Figure 1. Analyses of bovine lactoferrin (bLF) on lung cancer cell viability, morphological changes, and growth. (A) Effects of bLF over a range of concentrations (15, 7.5, 3.75, 1.875, and 0.9375 mg/mL) on the cell viability of A549, CL1–0 (both lung cancer cell lines), and Beas 2B cells (normal lung cells) after 24 h of incubation. The significance of difference was calculated by Scheffé’s test, and results with \( P < 0.05 \) were labeled with different letters and considered statistically significant. (B) A549 cells were treated without (a) or with (b: 15, c: 7.5, d: 3.75, e: 1.875, and f: 0.9375 mg/mL) bLF for 48 h. The cells were examined and photographed (100× magnification) under phase-contrast microscopy. (C) A549 cells treated without or with bLF (3 mg/mL) in 24-well microtiter plates for various time points (1, 4, 7, 8, 9, and 10 d) were cultured, and the total number of cells was plotted against time. Color version available in the online PDF.
Figure 2. Expressions of vascular endothelial growth factor mRNA (vegf) and protein (VEGF) in A549 cells treated with bovine lactoferrin (bLF) after 48 h of incubation. (A) The expression of vegf mRNA treated without or with various doses (10, 5, 2.5, 1.25, and 0.625 mg/mL) of bLF. The significance of difference was calculated by Scheffé's test; results with $P < 0.05$ were labeled with different letters and considered statistically significant. (B) The expression of VEGF protein treated without or with various doses (10, 5, 2.5, 1.25, and 0.625 mg/mL) of bLF as measured using Western blotting. (C) A549 cells treated with bLF (3 mg/mL) were cultured in Dulbecco's modified Eagle medium (DMEM) supplemented with 10% or 0.1% fetal bovine serum (FBS) under normal or hypoxic conditions (95% N₂ and 5% CO₂). The significance of difference was calculated by Scheffé's test; results with $P < 0.05$ were labeled with different letters and considered statistically significant.
Effects of bLF on Lung Cancer Cell Viability, Morphological Changes, and Growth

Two human lung adenocarcinoma cell lines, A549 and CL1–0, were treated with bLF (at 15, 7.5, 3.75, 1.875, and 0.9375 mg/mL) for 48 h. This treatment decreased cell viability in a concentration-dependent manner compared with untreated controls (Figure 1A). Additionally, the MTT assay revealed that concentrations up to 15 mg/mL of bLF treatment produced no significant cytotoxic effects on normal lung cells (Beas 2B). The median lethal dose (LD₅₀) values of bLF treatment were 3.2 and 5.6 mg/mL for A549 and CL1–0 cells, respectively (Figure 1A); bLF was able to successfully inhibit the growth of A549 and CL1–0 cells. Chang et al. (2004) showed that A549 cells have greater invasive and metastatic abilities than CL1–0 cells. Thus, in this study, we focused on elucidating the anticancer effect of bLF in A549 cells.

After the A549 cells were treated with bLF (10, 5, 2.5, 1.25, and 0.625 mg/mL) for 48 h, they underwent significant morphologic changes, as shown in Figure 1B. This result ruled out a possible cytotoxic effect of bLF in A549 lung cancer cells, supporting a negative effect of bLF on cell proliferation. To determine the effect of bLF on the growth of A549 cells, the cells were treated with (3 mg/mL) or without bLF in 24-well microtiter plates for various times (1, 4, 7, 8, 9, and 10 d), and the total number of cells was plotted (Figure 1C). From the log phase of the curve, the population doubling time of
A549 cells treated with or without bLF was 59.3 and 23.5 h, respectively, indicating that A549 cells treated with bLF grew more slowly than untreated A549 cells.

**bLF Suppresses VEGF Expression in A549 Lung Cancer Cells**

The effect of bLF on vEGF mRNA expression was investigated as shown in Figure 2A. Results showed that bLF inhibited expression of vEGF in a dose-dependent manner; approximately 12 and 75% reductions were observed at 1.25 and 5 mg/mL bLF, respectively. At concentrations up to 10 mg/mL, bLF almost completely inhibited the expression of vEGF mRNA in A549 cells. Additionally, in A549 cells treated with bLF (10, 5, 2.5, 1.25, and 0.625 mg/mL) for 48 h, the expression of VEGF protein decreased in a concentration-dependent manner compared with untreated control (Figure 2B). Results for VEGF protein expression were the same as those for vEGF mRNA expression.

Early stage cancer cells will continue to proliferate in vivo, leading to deficiencies in both nutrients and oxygen. To imitate the growth environment of the cancer cells in vivo, cells were cultured in DMEM supplemented with 10% FBS or 0.1% FBS in normoxia or hypoxia (95% N₂ and 5% CO₂) conditions. In the present study,

1Transgenic mice homozygous for the human vascular endothelial growth factor A165 isoform (hVEGF-A165+/+) were randomly assigned into 2 groups for treatment (n = 6): (1) transgenic mice treated with PBS as mock control (Tg/Mock) and (2) transgenic mice treated with bovine lactoferrin (bLF; Tg/bLF). After oral administration of bLF at 300 mg/kg of BW 3 times a week for 1.5 mo, mice were killed at 10.5 mo of age and lung tissues were collected for histopathology.

**Effects of bLF on Histopathology and Tumor Suppression in VEGF-Overexpressing Transgenic Mice**

We developed hVEGF-A165-overexpressing transgenic mice carrying the mcsps-hVegfA165-sv40poly(A) transgene (Figure 3A) to specifically express human VEGF-A165 mRNA (Figure 3B) and protein (Figure 3C) in lung Clara cells (bronchiolar exocrine cells), which would induce lung tumor formation in homozygous transgenic mice around 10.5 mo of age. Lung exteriors of wild-type mice and hVEGF-A165-overexpressing transgenic mice >10.5 mo are shown in the left-most panels of Figure 4. The lung tumors in the transgenic mice primarily included neoplasms growing on the periphery of the lung alveolus and adenomas growing on the site near the lung bronchus. In a lung alveolus on a lung bronchus of a transgenic mouse, some obvious, large-grained, pink cells were found (Figure 4B, middle panel). These pink cells are macrophages and are indicative of an inflammatory response. Results suggested that hVEGF-A165 is capable of promoting vascular permeability and an effective inflammatory response. Furthermore, after oral administration of bLF at 300 mg/kg of BW 3 times a week for 1.5 mo, the 10.5-mo-old transgenic mice (overexpressing hVEGF-A165) showed a dramatic decrease in solid tumor formation (16.7%; Table 1 and Figure 4C) compared with untreated transgenic mice (66.7%; Table 1 and Figure 4B).

Immunohistochemical analysis showed that VEGF was overexpressed in the Clara cells of lung tissues from transgenic mice (Figure 4B, right panel) compared with wild-type mice (Figure 4A, right panel). In hVEGF-A165-overexpressing transgenic mice, treatment with bLF (Figure 4C, right panel) significantly reduced VEGF overexpression in Clara cells compared with untreated transgenic mice.

**bLF Decreases vegf, IL-6, and TNF-α mRNA Transcripts in VEGF-Overexpressing Transgenic Mice**

In the lung cancer cell study, we found that the vegf mRNA expression was significantly decreased in A549 cells after treatment with bLF. We expected that bLF could inhibit vegf mRNA expression, which is responsible for cell proliferation. The mRNA expression levels of vegf, IL-6, and TNF-α were markedly decreased (P < 0.05) in the lungs of the Tg/bLF group compared with those of the Tg/Mock group; Figure 5A). Furthermore, Western blotting showed that the expression of VEGF was significantly decreased in the Tg/bLF group compared with the Tg/Mock group (Figure 5B), suggesting that angiogenesis may be blocked because of the inhibition of VEGF expression by treatment with bLF.
bLF Suppresses Cytokine Levels in VEGF-Overexpressing Transgenic Mice

The levels of VEGF-A, TNF-α, IL-4, IL-6, and IL-10 in the serum of Tg/bLF and Tg/Mock groups are shown in Figure 6. The VEGF-overexpressing transgenic mice that underwent oral administration of bLF showed a significant reduction in serum VEGF (30 pg/mL), TNF-α (466 pg/mL), IL-4 (410 pg/mL), IL-6 (377 pg/mL), and IL-10 (696 pg/mL) concentrations compared with the Tg/Mock group (P < 0.01). These results demonstrate that oral administration of bLF at 300 mg/kg of BW could decrease concentrations of VEGF-A, TNF-α, IL-4, IL-6, and IL-10, which may lead to restrictions in the growth of lung cancer cells.

Figure 5. Quantitative analyses of mRNA and protein expressions in the lung tissues of human vascular endothelial growth factor (VEGF) isoform A165 (hVEGF-A165)-overexpressing transgenic mice. (A) Real time-PCR validation of mRNA expression levels of *vegf*, *IL-6*, and tumor necrosis factor-α (*TNF-α*) in the lung tissues of the transgenic mice treated with PBS alone (Tg/Mock group) or with bLF at 300 mg/kg of BW 3 times a week for 1.5 mo (Tg/bLF group). The cDNA of β-actin was used as an internal control. Mean ± SEM (n = 6); *P < 0.05 vs. Tg/Mock group. (B) Expression of VEGF protein in the lung tissues of the Tg/Mock and Tg/bLF groups measured using Western blotting. Mouse GAPDH was used an internal control.

DISCUSSION

In the initial stages of lung cancer, cancer cells keep proliferating and thus experience deficiencies in both nutrient and oxygen, leading to massive cell death. When cancer cells secrete a large amount of VEGF-A165, vasculogenesis is induced to provide sufficient nutrients and oxygen to the tumor, therefore increasing the speed of tumor growth (Ferrara and Davis-Smyth, 1997). In this study, we demonstrated that bLF slowed the proliferation of A549 human lung cancer cells by decreasing expression of *vegf* mRNA and VEGF protein in a dose-dependent manner (Figure 1). Because bLF exhibited no cytotoxicity on normal human bronchial epithelial cells under the same conditions, bLF warrants further
Bovine lactoferrin is a multifunctional protein without side effects. Yamauchi et al. (2000) found that administration of 2,000 mg/kg per day of bLF has no adverse effects in both sexes in rats and results in no apparent changes in food consumption, BW, ophthalmology, and urinalysis, including 1-d water intake, hematology (red blood cells, hemoglobin, hematocrit, mean corpuscular volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, prothrombin time, activated partial thromboplastin time, and white blood cells), blood chemistry [glutamic oxaloacetic transaminase (GOT), glutamate pyruvate transaminase (GPT), lactate dehydrogenase (LDH), alkaline phosphatase (ALP), total cholesterol, total bilirubin, BUN, inorganic phosphorus, total protein, and albumin:globulin ratio], necropsy, organ weights, and histopathology. Furthermore, Shimamura et al. (2004) demonstrated that administration of 300 mg/kg per day of bLF suppresses tumor growth and metastasis in the mouse, which may be partly mediated by angiogenesis inhibition. In this study, we investigated the inhibition of pulmonary tumor formation through treatment with 300 mg/kg per day of bLF suppresses tumor growth and metastasis in the mouse, which may be partly mediated by angiogenesis inhibition. In this study, we investigated the inhibition of pulmonary tumor formation through treatment with 300 mg/kg per day of bLF in a hVEGF-A<sub>165</sub>-overexpressing transgenic mice model to present in situ lung tumors. We found that oral administration of bLF at 300 mg/kg of BW 3 times a week for 1.5 mo to 10.5-mo-old hVEGF-A<sub>165</sub>-overexpressing transgenic mice led to a dramatic decrease in solid tumor formation compared with untreated transgenic mice (Table 1). Histological analysis showed that treatment with bLF reduced lung tumor formation and inflammation in hVEGF-A<sub>165</sub>-overexpressing transgenic mice (Figure 4). Moreover, immunohistochemical analysis showed that oral administration of bLF could reduce VEGF overexpression in Clara cells of the lung, which is related to vasculogenesis and angiogenesis. These processes are vital factors in the formation of tumors and in tumor growth, invasion, and metastasis. Bovine lactoferrin may act as an angiogenesis inhibitor, and thus have considerable potential in the treatment of lung cancer, because angiogenesis is necessary for the growth of a tumor beyond a few millimeters in diameter. Without angiogenesis, the tumor cannot access increased levels of oxygen and nutrients or remove waste. Previous studies also reported that bLF inhibited lung metastases, which was attributed to its antiangiogenic properties (Yoo et al., 1997). Shimamura et al. (2004) suggested that bLF participates as a regulator of angiogenesis, possibly by blocking endothelial function and inducing IL-18 production.

In this study, we demonstrated that VEGF-A, TNF-α, IL-4, IL-6, and IL-10 could be decreased by bLF (Figure 6), which might inhibit cancer cell proliferation and stimulate cancer cell apoptosis (Bohlen et al., 2000; Alas et al., 2001; Sredni et al., 2004; Hong et al., 2007; Sethi et al., 2008). Additionally, treatment with bLF reduced the levels of these cytokines, resulting in restricted lung cancer growth. This may be a
potential use for exploiting the activity of bLF against lung cancer for therapeutic purposes.

CONCLUSIONS

We found that bLF inhibited the expression of vegf mRNA and VEGF protein, which regulates angiogenesis. The suppression of angiogenesis by bLF is mediated by VEGF-A, and bLF inhibits tumor-induced angiogenesis in mice. These effects might comprise one of the mechanisms for the anticancer functions of bLF. This is the first paper using the in situ lung tumor model created by Clara cell-specific VEGF overexpression transgenic mice to understand the antitumor therapeutic effects of bLF through the suppression of inflammation and the VEGF pathway. Further study is underway to fully evaluate the mechanisms of bLF effects on tumorigenesis and to examine the potential use of bLF as a therapeutic agent.
