ABSTRACT

Bovine mastitis undermines udder health, jeopardizes milk production, and entails prohibitive costs, estimated at $2 billion per year in the dairy industry of the United States. Despite intensive research, the dairy industry has not managed to eradicate the 3 major bovine mastitis-inducing pathogens: *Staphylococcus aureus*, *Streptococcus uberis*, and *Escherichia coli*. In this study, the antimicrobial efficacy of a newly formulated biphenomycin compound (AIC102827) was assessed against intramammary *Staph. aureus*, *Strep. uberis*, and *E. coli* infections, using an experimental mouse mastitis model. Based on its effective and protective doses, AIC102827 applied into the mammary gland was most efficient to treat *Staph. aureus*, but also adequately reduced growth of *Strep. uberis* or *E. coli*, indicating its potential as a broad-spectrum candidate to treat staphylococcal, streptococcal, and coliform mastitis in dairy cattle.  

Key words: antimicrobial therapy, *Staphylococcus aureus*, *Streptococcus uberis*, *Escherichia coli*

Short Communication

Mammary gland inflammation, or mastitis, provokes detrimental damage to mammary epithelial cells and results in highly impaired milk production. As the most common disease in dairy cows, mastitis is the principal cause of economic losses in the dairy industry (Piepers et al., 2007; Pinzón-Sánchez et al., 2011). Clinical mastitis caused by environmental pathogens such as *Streptococcus uberis* and *Escherichia coli* can mostly be cured by antibiotic therapy (Pyörälä, 2009). Nevertheless, the incidence of coliform mastitis has been increasing relentlessly, and multidrug resistance is a typical feature for *E. coli* (Bradley, 2002; Saini et al., 2012). Although use of the preventive measures in the well-known 10-point checklist of the National Mastitis Council (NMC, 2006) has significantly improved the incidence of mastitis induced by contagious pathogens such as *Staphylococcus aureus*, staphylococcal mastitis is still frequently observed (Hogeveen et al., 2010; Zadoks et al., 2011). Therefore, novel antimicrobial therapies remain highly desired for treatment of not only *Strep. uberis* and *E. coli* mastitis but also *Staph. aureus* mastitis.

The antimicrobial AIC102827 belongs to the cyclopeptide biphenomycin class (Ezaki et al., 1985), acting at the level of bacterial protein synthesis; that is, inhibition of the thermo-unstable elongation factor (EF-Tu). Specifically, the thermo-unstable elongation factor mediates the entry of the aminoacyl-transfer (t)RNA into the free A-site of the ribosome (Agirrezabal and Frank, 2009). This mode of action makes no distinction between gram-positive and gram-negative pathogens, suggesting the potential for efficient antibiotic activity against gram-positive *Staph. aureus* and *Strep. uberis* and gram-negative *E. coli*. The objective of the current study was to screen, both in vitro and in vivo, the intramammary efficacy of the novel candidate antimicrobial AIC102827 against the bovine mastitis pathogens *Staph. aureus*, *Strep. uberis*, and *E. coli*. Bovine mastitis studies are time consuming and extremely costly. Therefore, the mouse model for bovine mastitis, which has been recognized as a fast, cheap, and reproducible intermediate in vivo alternative for antimicrobial compound efficacy studies in cattle (Brouillette et al., 2004; Notebaert et al., 2008; Demon et al., 2012), was applied as an elegant screening tool in the current study.

In the present study, the excipient (hydrogel) and different concentrations of AIC102827 (2, 4, 8, and 12 mg/mL) were provided as ready-to-use suspensions by AiCuris GmbH & Co. (Wuppertal, Germany). *Staphylococcus aureus* Newbould 305 (ATCC 29740), *Strep. uberis* NADC C-1 (ATCC 27958), and *E. coli* P4:O32 were used for infection of mice (challenge isolates). These bacterial strains were originally isolated from clinical mastitis cases (Prasad and Newbould, 1968; Bramley, 1976; McDonald and McDonald, 1976). Over-
night cultures of the bacteria were diluted in sterile PBS and quantified by flow cytometry (BD Biosciences, Erembodegem, Belgium), as described in detail by Demon et al. (2012). In vitro determination of the MIC of AIC102827 against the challenge isolates *Staphylococcus aureus* Newbould 305, *Streptococcus uberis* NADC C-1, and *Escherichia coli* P4:O32, and a random selection of recent bovine mastitis field isolates (n = 10 for each species) was performed using the Mueller-Hinton agar dilution assay according to Clinical and Laboratory Standards Institute guidelines (CLSI, 2008). The procedures for mouse mammary gland infection, postmortem mammary gland homogenization, and bacterial quantification have been described recently by our group (Demon et al., 2012). Briefly, CD-1 lactating mice (Harlan Laboratories Inc., Horst, the Netherlands) were anesthetized and intraductally inoculated with approximately 150 CFU of challenge isolate in 100 μL of PBS in both glands of the fourth abdominal mammary gland pair. Similarly, 100 μL of the excipient and test doses of AIC102827 were instilled at 4 h after bacterial inoculation. After killing of the mice at 14 h posttreatment, mammary glands were harvested, weighed, and homogenized on ice in sterile PBS. Bacterial counts (CFU) were obtained after quantification of serial log_{10} dilutions of mammary gland homogenates on tryptic soy agar plates and transformation of the raw counts into base 10 logarithmic (log_{10}) values. The detection limit was 1.7 log_{10} CFU/g of gland. In the dose-titration studies, a group with bacteria-infected, excipient-treated mice (excipient control group) was compared with 3 test groups, in which mice were infected with bacteria and treated with a particular dose of AIC102827. In the intra-experimental comparison study, the excipient control group was compared with one test group, in which mice were infected with bacteria and treated with 800 μg/gland of AIC102827. The groups in the different studies were composed of 4 mice (8 mammary glands), except the 3 mice (6 glands) in the 800 μg/gland test group in the *E. coli* dose-titration study. The animal experiments were approved by the Ethical Committee of the Faculty of Veterinary Medicine, Ghent University, Merelbeke, Belgium (EC2009/133). To evaluate the dose-response relationship for the antimicrobial, the effective dose (ED)_{2 log_{10}} ED_{log_{10}}, protective dose (PD)_{50} and PD_{100} values were calculated from the dose-titration studies. The ED_{2 log_{10}} and ED_{4 log_{10}} values are the concentrations of AIC102827 needed to reduce the mean bacterial count from the excipient control group by 2 log_{10} and 4 log_{10} CFU/g of gland, respectively. The PD_{50} and PD_{100} are the doses of AIC102827 needed to observe, respectively, 50 and 100% of cleared mammary glands (with mean bacterial count below the detection limit). The model parameters were calculated by nonlinear regression analysis using Microsoft Excel software (Microsoft Corp., Redmond, WA). The models that fitted best; that is, that yielded the highest R^2 value, with the dose-response relationship of the antibiotic were polynomial for *Staphylococcus aureus* Newbould 305 (y = 7.10^{-6}x^2 − 0.0471x + 8.5966) and *Streptococcus uberis* NADC C-1 (y = 5.10^{-6}x^2 − 0.0101x + 6.1556) and exponential for *E. coli* P4:O32 (y = 8.6977e^{-0.002x}). The ED_{2 log_{10}} and ED_{4 log_{10}} values were then computed by calculating x from these models, in which y is replaced by z − 2 and z − 4, respectively, with z being the mean bacterial count (log_{10} CFU/g of gland) from the excipient control group. To determine the volume of the secretory fluid in the bacterially infected mammary gland, mice (n = 8) were intraductally infected with *Staphylococcus aureus* Newbould 305 as described. Mammary glands (n = 15; 1 gland was omitted due to improper inoculation) were harvested at 4 h postinoculation. The glands were weighed, placed on a cell strainer of 40 μm, and centrifuged at 2,000 × g for 1 h to expel their milk content. After centrifugation, the glands were weighed again and subtracted from the gland weight before centrifugation. The resulting weight was divided by the density of mouse milk (1.06 mg/mL) to calculate the corresponding volume.

Table 1 reports MIC values of AIC102827, the newly formulated antimicrobial from the biphenomycin class, against the 3 major bovine mastitis pathogens. The MIC values of AIC102827 against 10 bovine mastitis field isolates of *Staphylococcus aureus*, *Streptococcus uberis*, and *Escherichia coli* were 4 to 8, ≥ 16, and 2 to 4 μg/mL, respectively. These MIC values illustrate efficient in vitro antimicrobial activity of AIC102827 against *Staphylococcus aureus* and *Escherichia coli*, but less adequate activity against *Streptococcus uberis*. The adequate activity of AIC102827 against *Staphylococcus aureus* and *Escherichia coli* indicates its ability to act against both gram-positive and gram-negative bacteria. However, the inadequate activity against *Streptococcus uberis* shows that, although AIC102827 inhibits a universal bacterial growth mechanism, species-specific characteristics are involved in the susceptibility to the antimicrobial. The MIC values of AIC102827 against the mouse mastitis challenge isolates of *Staphylococcus aureus* Newbould 305, *Streptococcus uberis* NADC C-1, and *Escherichia coli* P4:O32 were 4, > 16, and 4 μg/mL, respectively, and strongly correlated with the sensitivity of the bovine mastitis field isolates, indicating the suitability of the latter as reference strains in the current in vivo mouse mastitis study. The in vivo dose-responses of mouse mastitis induced by *Staphylococcus aureus* Newbould 305, *Streptococcus uberis* NADC C-1, and *Escherichia coli* P4:O32 to hydrogel-suspended AIC102827 were analyzed in 3 separate dose titration studies (Figure 1A to C). These data were used to calculate the ED_{2 log_{10}} ED_{4 log_{10}}, PD_{50}, and PD_{100} values (Table 1). The ED_{2 log_{10}} value (corresponding to 99% bacterial clearance) of
AIC102827 was 45, 215, and 130 μg/gland for *Staph. aureus*, *Strep. uberis*, and *E. coli*, respectively. These values indicate that AIC102827 can clear 99% of the *Staph. aureus* bacteria from the lactating mammary gland, even at a low dose, whereas a higher dose is needed to clear *Strep. uberis* and *E. coli*. In line with this finding, the ED*4log10* value (corresponding to 99.99% bacterial clearance) of AIC102827 was 100, 530, and 310 μg/gland for *Staph. aureus*, *Strep. uberis*, and *E. coli*, respectively. The PD*50* and PD*100* values of AIC102827 for the 3 mouse mastitis challenge isolates additionally indicated that its intramammary treatment is more efficient in curing glands infected by *Staph. aureus* than by *Strep. uberis* or *E. coli*. An intra-experimental study with one selected dose of AIC102827 was then performed to evaluate reproducibility and compare the antimicrobial efficacy of AIC102827 between the 3 pathogens in a study with minimal variability of experimental parameters such as the health status of the mice and environmental conditions such as humidity and temperature (Figure 1D). An AIC102827 dose of 800 μg/gland was selected for the intra-experimental comparison study, because it showed reduction of the bacterial load virtually to the detection limit in most mammary glands in the separate dose-titration studies. For all 3 species, the mean bacterial counts (log10 cfu/g of gland) in the intra-experimental study (Figure 1D) closely approximated their respective means in the dose-titration study (Figure 1A to C), illustrating the reproducibility of our data. Together, our in vitro MIC and in vivo mouse data indicate adequate efficacy of AIC102827 against the 3 mouse mastitis challenge isolates.

The antimicrobial AIC102827 indicated similar in vitro MIC for *Staph. aureus* Newbould 305 and *E. coli* P4:O32. Consequently, analogous in vivo antimicrobial activity was expected against both pathogens. However, AIC102827 was less effective against *E. coli* than against *Staph. aureus* in the in vivo study. In contrast, efficacy against *Strep. uberis* in vivo was higher than expected based on the in vitro data. Together, these observations indicate that the mammary gland environment positively influences antimicrobial activity against the gram-positive bacteria and negatively affects activity against the gram-negative *E. coli*. A possible explanation for the increased in vivo activity against *Staph. aureus* and *Strep. uberis* could be that the concentration of AIC102827 in milk greatly exceeds the in vitro MIC required to inhibit bacterial growth. To assess this hypothesis, we evaluated the intramammary antimicrobial concentration in the bacterially infected mammary gland at 4 h postinfection; that is, at the time of compound treatment. On average, 52 μL (±19 μL) of secretory fluid was observed in the infected mammary gland, which had a mean weight of 635 mg (±163 mg) at the time of treatment (Figure 2). Although substantial variability in gland volume was seen, these data indicate that the concentration of the compound suspension, which is injected in a volume of 100 μL, is reduced by approximately 30% after injection in the mammary gland. Treatment with the 8 mg/mL suspension led to a concentration of approximately 5 mg/mL in the mammary gland and is several-hundred-fold higher than the concentration that is used in in vitro experiments (in the μg/mL range) to determine the MIC values, corroborating this hypothesis. However, this does not explain the potentially lower in vivo antimicrobial efficacy against *E. coli*. The milk environment of the mammary gland is known to influence the in vivo efficacy of an antimicrobial agent. Critical aspects influenced by the milk matrix are local immune cell interactions, bacterial growth, and pharmacokinetic parameters (adsorption, distribution, metabolism, and excretion) of the antimicrobial (Brouillette and Malouin, 2005; Gehring and Smith, 2006; Van Bambeke et al., 2006). In this context, the extracellular residing

![Table 1. Antimicrobial efficacy of AIC102827 against *Staphylococcus aureus*, *Streptococcus uberis*, and *Escherichia coli* evaluated in vitro by determination of MIC values and in vivo by analyzing effective and protective doses using the mouse mastitis model](attachment:image)
E. coli has become better adapted to the milk environment than the typically intracellularly residing gram-positive pathogens *Staph. aureus* and *Strep. uberis*, at least partially clarifying the potentially lower than expected antimicrobial efficacy against *E. coli* observed in the current study. The observation that the in vitro antimicrobial activity of AIC102827 for *Staph. aureus*, *Strep. uberis*, or *E. coli* did not directly correlate with its in vivo efficacy corroborates previous reports by our group and others (Apparao et al., 2009; Pyörälä, 2009; Demon et al., 2012). Hence, our current data again highlight the importance of in vivo studies in addition to in vitro studies to screen antimicrobial candidates.

Several studies in cows describe strain-specific associations for *Staph. aureus*, *Strep. uberis*, and *E. coli* with respect to clinical signs, persistence, and response...
appropriate formulation in dairy cattle is now required for the efficacy assessment of this promising compound in an experiment with a strain of the 3 major bovine mastitis pathogens, Staph. aureus, Strep. uberis, and E. coli. The field efficacy assessment of this promising compound in an appropriate formulation in dairy cattle is now required to validate these innovative intermediate data in the target species.
