ABSTRACT

*Lactobacillus plantarum* is a lactic acid bacterium that can be found during cheese ripening. Lipolysis of milk triacylglycerols to free fatty acids during cheese ripening has fundamental consequences on cheese flavor. In the present study, the gene *lp_1760*, encoding a putative esterase or lipase, was cloned and expressed in *Escherichia coli* BL21 (DE3) and the overproduced *Lp_1760* protein was biochemically characterized. *Lp_1760* hydrolyzed *p*-nitrophenyl esters of fatty acids from C2 to C16, with a preference for *p*-nitrophenyl butyrate. On triglycerides, *Lp_1760* showed higher activity on tributyrin than on triacetin. Although optimal conditions for activity were 45°C and pH 7, *Lp_1760* retains activity under conditions commonly found during cheese making and ripening. The *Lp_1760* showed more than 50% activity at 5°C and exhibited thermal stability at high temperatures. Enzymatic activity was strongly inhibited by sodium dodecyl sulfate and phenylmethylsulfonyl fluoride. The *Lp_1760* tributyrin esterase showed high activity in the presence of NaCl, lactic acid, and calcium chloride. The results suggest that *Lp_1760* might be a useful tributyrin esterase to be used in cheese manufacturing.

Key words: lipolysis, cheese ripening, aroma, triacylglycerol, lactic acid bacteria

INTRODUCTION

The characteristic flavor of cheese is the result of the breakdown of protein, fat, and carbohydrates by native milk enzymes, added enzymes, starter bacteria, and the secondary microbiota of cheese (Fox and Wallace, 1997). Lipolysis of milk triacylglycerols to FFA during cheese ripening is an important biochemical process that contributes directly to its sensory characteristics (Collins et al., 2003). Free fatty acids are important sensory compounds by themselves, and also as precursors of other volatiles and esters (McSweeney and Sousa, 2000). The release of FFA during cheese ripening by the combined action of lipolytic enzymes contributes to the development of flavor. Lipolytic enzymes include lipases, which catalyze the hydrolysis of water-insoluble long-chain triglycerols. The contribution of the native milk lipase to lipolysis in cheese is significant only in these varieties produced with raw milk, as this enzyme is inactivated during heat treatment. In other varieties, such as Cheddar cheese, only a low level of milk fat hydrolysis occurs due to the weak lipolytic activities of the starter and nonstarter bacteria (Crow et al., 1994).

Lactic acid bacteria are a source of esterase and lipases. Enzymes from *Lactococcus lactis* (Tsakalidou and Kalantzopoulos, 1992; Holland and Coolbear, 1996; Fernández et al., 2000), *Lactobacillus casei* (Castillo et al., 1999), *Lactobacillus fermentum* (Gobbetti et al., 1997), *Streptococcus thermophilus* (Liu et al., 2001), and *Micrococcus* spp. (Fernández et al., 2004) have been purified and characterized. Likewise, esterases and lipases from *Lactobacillus plantarum* have been partially purified (Andersen et al., 1995), purified (Oterholm et al., 1967, 1968; Andersen et al., 1995; Gobbetti et al., 1996, 1997; Lopes et al., 1999, 2002), or recombinantly produced (Brod et al., 2010; Benavente et al., 2013; Esteban-Torres et al., 2013; Navarro-González et al., 2013). Among the lipases described from *Lb. plantarum* (Oterholm et al., 1967, 1968; Andersen et al., 1995; Gobbetti et al., 1996, 1997; Lopes et al., 2002), none have been genetically identified so far.

The genome sequence of *Lb. plantarum* WCFS1 was published in 2003 (Kleerebezem et al., 2003) and more than 20 putative esterase or lipase genes were annotated on the basis of similarity searches. Although an operational distinction is made between esterases, which preferentially break the ester bonds of shorter chain acyl substrates at least partly soluble in water, and lipases, which display maximal activity toward water-insoluble long-chain triglycerides, no fundamental biochemical difference exists (Bornscheuer, 2002).
From a structural viewpoint, both esterases and lipases are members of the α or β hydrolase superfamily and share common catalytic machinery for ester hydrolysis and formation (Bornscheuer, 2002). Classifications based on sequence similarities do not separate the 2 classes of enzymes. The definitive approach to assigning a specific molecular function to a predicted open reading frame is to biochemically characterize the corresponding protein.

In this regard, the objective of the current study was to determine the functional features of the putative esterase or lipase Lp_1760 from *Lb. plantarum* WCFS1 through biochemical characterization of the recombinantly expressed protein. With a view to applying this esterase under conditions found during cheese making and ripening, enzyme activity under physicochemical conditions frequently encountered in cheese was studied.

**MATERIALS AND METHODS**

**Bacterial Strains, Plasmids, Growth Media, and Materials**

*Lactobacillus plantarum* WCFS1 used through the current study was provided by M. Kleerebezem (Nizo Food Research, Wageningen, the Netherlands). *Escherichia coli* DH10B was used as host strain for all DNA manipulations. *Escherichia coli* BL21 (DE3) was used for heterologous expression in the pURI3-Cter vector (Curiel et al., 2011). The *Lb. plantarum* strain was grown in de Man, Rogosa, Sharpe medium (Pronadisa, Madrid, Spain) adjusted to pH 6.5 and incubated at 30°C. *Escherichia coli* strains were cultured in Luria-Bertani medium at 37°C with shaking at 200 rpm. When required, ampicillin was added to the medium at a concentration of 100 μg/mL.

Plasmid DNA was extracted by a High Pure Plasmid Isolation Kit (Roche, Mannheim, Germany). The PCR product was purified with a QIAquick gel extraction kit (Qiagen, Hilden, Germany). Oligonucleotides were purchased from Eurofins MWG Operon (Ebersberg, Germany). *DpnI* and HS Prime Star DNA polymerase were obtained from TaKaRa (Shiga, Japan). His-tagged protein was purified by a Talon Superflow resin (Clontech, Mountain View, CA).

**Lp_1760 Gene Cloning and Expression**

Genomic DNA from *Lb. plantarum* WCFS1 was extracted. The gene encoding a putative lipase or esterase (*lp_1760*) in *Lb. plantarum* WCFS1 was amplified by PCR by using the primers 1220 (5’-TAACTTTTAGAAGGAGATATACTATatgcaaatctaatccgacact) and 1221 (5’-GCTATTAATGATGATGATGATGATGATGATGATGATGATGATGATG- Gatttaaatctgaaagaaa; the nucleotides pairing the expression vector sequence are indicated in italics and the nucleotides pairing the *lp_1760* gene sequence are written in lowercase letters). Prime Star HS DNA polymerase (TaKaRa) was used for the PCR amplification. The 753-bp purified PCR product was inserted into the pURI3-Cter vector using a restriction enzyme- and ligation-free cloning strategy (Curiel et al., 2011). The vector produces recombinant proteins having a 6-bis-histidine affinity tag in their C-termini. *Escherichia coli* DH10B chemically competent cells were transformed, recombinant plasmids were isolated, and those containing the correct insert were identified by size, verified by DNA sequencing, and then transformed into *E. coli* BL21 (DE3) cells for expression.

**Lp_1760 Protein Purification**

Protein expression of the *lp_1760* gene was made using *E. coli* BL21 (DE3) cells as the host strain. Cells carrying the recombinant plasmid pURI3-Cter-1760 were grown at 37°C in Luria-Bertani medium containing 100 μg/mL of ampicillin on a rotary shaker (200 rpm) until an optical density at 600 nm of 0.4 was reached. Isopropyl-β-D-thiogalactopyranoside was added to a final concentration of 0.4 mM and protein induction was continued at 22°C for 18 h. The induced cells were harvested by centrifugation (8,000 × g, 15 min, 4°C). The cells were resuspended in phosphate buffer (50 mM, pH 7) containing 300 mM NaCl and disrupted by French press passages (3 times at 1,100 psi). The insoluble fraction of the lysate was removed by centrifugation at 47,000 × g for 30 min at 4°C and the supernatant was filtered through a 0.2-μm pore filter and then loaded onto a Talon Superflow resin (Clontech). The resin was equilibrated in phosphate buffer (50 mM, pH 7) containing 300 mM NaCl and 10 mM imidazole to improve the interaction specificity in the affinity chromatography step. The bound enzyme was eluted using 150 mM imidazole in the same buffer. The purity of the enzyme was determined by SDS-PAGE in Tris-glycine buffer. Fractions containing the His-tagged protein were pooled, dialyzed against phosphate buffer (50 mM, pH 7) containing 300 mM NaCl, and analyzed for esterase activity.

**Enzyme Assay**

Esterase activity was determined by a spectrophotometric method as described previously (Esteban-Torres et al., 2013); however, *p*-nitrophenyl butyrate (Sigma-Aldrich, Steinheim, Germany) was used as substrate.
**Results and Discussion**

**Production and Characterization of Lp_1760 Esterase**

*Lactobacillus plantarum* is a flexible and versatile bacterial species that is encountered in a wide variety of environmental niches, including some dairy, meat, and plant fermentations. The ecological flexibility of *Lb. plantarum* is clear by the observation that this species has one of the largest genomes known among lactic acid bacteria (Kleerebezem et al., 2003). This large genome codifies enzymatic activities that could develop a fundamental role in food fermentations, such as esterases or lipases. When the reported sequence of the *Lb. plantarum* WCFS1 genome was analyzed, numerous open reading frames (ORF) encoding putative esterases or lipases were found. One of the first ORF present in all the available *Lb. plantarum* genomes is *lp_1760*, predicted to encode a 250-AA sequence protein with a theoretical molecular mass of 28.8 kDa. The deduced AA sequence of *Lp_1760* lacked an N-terminal secretion signal sequence suggesting that this enzyme is located intracellularly. The AA sequence of *Lp_1760* showed a 56% identity to a putative lipase or esterase from *Lactobacillus sakei* 23K (accession Q38VR0) or a 52% identity to a hydrolase from *Enterococcus faecalis* ATCC 6055 (accession R3KRQ5; data not shown).

The *lp_1760* gene was cloned into the pURI3-Cter expression vector by a ligation-free cloning strategy described previously (Curiel et al., 2011). The vector incorporates the DNA sequence encoding hexa-histidine to create a His-tagged fusion enzyme for further purification steps. The *lp_1760* gene was expressed under the control of an isopropyl-β-d-thiogalactopyranoside-inducible promoter. Cell extracts were used to detect the presence of overproduced proteins by SDS-PAGE analysis. An overproduced protein with an apparent molecular mass around 28 kDa was apparent in cells harboring pURI3-Cter-1760 (Figure 1). The recombinant protein was purified by a metal affinity chromatography resin, and eluted with phosphate buffer (50 mM, pH 7) containing 300 mM NaCl and 150 mM imidazole. The eluted His6-tagged *Lp_1760* was dialyzed and observed as a single band on SDS-PAGE (Figure 1). Routinely, the yield of purification is about 8 mg/L of purified protein.

The purified *Lp_1760* protein was biochemically characterized. Substrate specificity was determined using *p*-nitrophenyl-linked esters of various acyl chain lengths (C2 to C16) at 37°C (Figure 2). *Lp_1760* showed activity on all the acyl esters assayed, exhibiting significant activity on *p*-nitrophenyl palmitate.
The observed activity on long-chain acyl esters confirmed that Lp_1760 is a true lipase. For the sake of comparison, we determined spectrophotometrically the kinetic parameters for the most reliable substrates, C2 and C4. In both cases, Lp_1760 exhibited hyperbolic Michaelis-Menten kinetics (not shown). The kinetic parameters are shown in Table 1. From the values of these parameters it can be deduced that the catalytic efficiency ($k_{cat}/K_M$) for $p$-nitrophenyl butyrate hydrolysis is around 2-fold that observed for $p$-nitrophenyl acetate hydrolysis, which is due to a lower $K_M$ for $p$-nitrophenyl butyrate as $k_{cat}$ is essentially the same.

Esterase activity was revealed when the hydrolysis of esters present in the library were assayed. Lp_1760 showed highest activity on tributyrin, although in triacetin 30% of the tributyrin activity was observed (data not shown). Apart from tributyrin and triacetin, from the 40 esters assayed, only methyl hydroxyacetate, phenyl acetate, and vinyl octanoate were minimally hydrolyzed (data not shown). Tributyrin is a true fat and the simplest triglyceride occurring in natural fats and oils. The principal lipids of milk are triacylglycerides, which may represent up to 98% of the total lipids (Collins et al., 2003). Triacylglycerides are esters of glycerols composed of a glycerol backbone with 3 FA attached. Tributyrin is a common constituent of lipase testing media as it is easily dispersed in water (Samad et al., 1989). Tributyrin esterases from Lb. plantarum have been isolated and partially purified previously (Andersen et al., 1995; Gobbetti et al., 1996, 1997; Lopes et al., 2002); however, they have not been genetically identified so far.

Regarding the dependence on pH of the hydrolytic activity, the lipase was active within the range between 3 and 8, exhibiting an optimal pH around 7 (Figure 3A). Lipases from Lb. plantarum characterized so far have optimal temperatures at 30 (Lopes et al., 1999), 35 (Gobbetti et al., 1996, 1997), or 37°C (Andersen et al., 1995). In contrast, maximal activity of Lp_1760 was observed at 45°C.

$^1$ $V_{max}$ = maximum reaction velocity; $K_M$ = Michaelis constant; $k_{cat}$ = catalytic constant.

$^2$ Enzyme activities were determined at 45°C in 50 mM sodium phosphate buffer, pH 7.0. Results are the mean value ± SD from 3 independent experiments.
More interestingly, Lp_1760 exhibited more than 50% of the maximal activity at 5°C, and the activity only decreased to 40% at 65°C. The high esterase activity observed within this broad range of temperatures makes this lipase a good candidate for industrial applications. Note that thermophilicity is related to the capacity of the enzyme to hydrolyze the substrate at high temperatures, whereas thermal stability is defined as an enzyme’s ability to resist thermal unfolding in the absence of its substrate (Dotsenko et al., 2012). Figure 3C shows how Lp_1760 exhibited high thermal stability under prolonged incubation at temperatures up to 45°C (Figure 3C).

The effects of several ions and additives on Lp_1760 activity are provided in Table 2. Compared with the enzyme incubated in 50 mM phosphate buffer pH 7, the enzymatic activity was not significantly increased by any of the ions or additives assayed. However, Lp_1760 activity was significantly inhibited by Hg2+, Zn2+, and Cu2+ ions and greatly inhibited by SDS or PMSF. Inactivation of the tributyrin esterase by PMSF suggests that a serine residue is involved in the catalytic mechanisms of the enzyme. This is highly probable, as most of the esterases and lipases have been previously characterized as having a Ser-Asp-His catalytic triad (Bornscheuer, 2002).

**Activity of Lp_1760 in the Presence of Conditions Found During Cheese Making and Ripening**

Unlike many processed food products for which stability is the key criterion, cheese is a biochemically dynamic product and undergoes significant changes during its ripening period. Lipolysis, or rather the extent to which it occurs during cheese ripening, is an important factor in the development of the correct and characteristic flavor profile of most cheese varieties. The use of exogenous lipases, microbial among them,

has been reported in the scientific literature for the manufacture of a variety of cheese to accelerate ripening or to develop characteristic flavors (Law, 2001; Hernández et al., 2005).

To ascertain the possible usefulness of Lp_1760 lipase during cheese making and ripening, the influence on its activity of the conditions and compound present on these processes was studied. Cheese-making processes subject microorganisms, and their enzymes, to adverse environmental conditions (such as acid or osmotic stress) which affect their technological performances. Lowering the pH in lactic acid fermentations may reduce the activity or completely inactivate enzymes that could generate either flavor components or flavor precursor compounds. The pH of cheese is controlled by the interactive effects of several critical factors, including the amount of lactic acid, calcium phosphate and proteins, the salt sensitivity of the starter culture, and the level and duration of salting (Hou et al., 2012). Figure 3 indicates that Lp_1760 exhibited 40% of its maximal activity at the pH usual during cheese making or ripening (pH near 5).

In relation to temperature, cheese ripening temperature is characteristic of each cheese variety. As an example, Cheddar-type cheeses may be cured or ripened at up to 15°C for a period of several months, whereas Swiss-type cheeses are cured at 22 to 23°C. The ripening temperature could be different from the storage or distribution temperature. It is recommended that pasteurized milk cheeses with <50% moisture, traditional levels of salt, starter culture, pH, and fat be allowed to be distributed at a temperature not exceeding 30°C (Johnson et al., 2009). At 15 to 30°C, Lp_1760 showed 50 to 70% of its maximal activity, which makes it adequate for these processes.

Due to its industrial relevance, a better knowledge of the influence of compounds present during cheese making or ripening is important. The influence on Lp_1760 activity by compounds present in these processes (such as NaCl, lactic acid, or calcium chloride) was also studied.

One of the final steps in the cheese-making process is the addition of salts. In dry-salted cheese, such as Cheddar, the salt is added directly to the curds just before hooping and pressing. In other types of cheese, the salt is added by submerging the cheese in brine (up to 20% NaCl) for an appropriate period of time and allowing salt to penetrate slowly during brining and the subsequent storage period. Finally, some cheeses have salt rubbed on the outer side of the cheese (Johnson et al., 2009). The influence of NaCl on Lp_1760 activity has been analyzed. Salt concentrations up to 10% increase lipase activity (Figure 4A). Contrarily, concentrations higher than 10% partially inhibited esterase activity; however, Lp_1760 retained half of the maximal activity at a 25% NaCl concentration. At salt concentrations usual on final cheeses, the activity of Lp_1760 is increased.

In relation to lactic acid, starter bacteria are used to ferment the lactose to lactic acid. The rate and extent of acid development is controlled by the cheese maker to produce the final desired body, texture, and flavor characteristics of the cheese. Total lactate levels increased significantly with ripening time. The increase in lactate content with ripening time is consistent with the decrease in lactose levels, which is metabolized to lactic acid during ripening by starter and nonstarter bacte-
L. plantarum activity. Lactic acid content from 1 to 1.5% (wt/wt) has been described during ripening of Cheddar cheese (Hou et al., 2012). At these lactic acid concentrations, Lp_1760 exhibited fully enzymatic activity (Figure 4B).

Calcium chloride is usually added to cheese-milk during cheese making to assist coagulation, improve the cheese-making process, or increase the yield. The normal range of calcium addition spans from 0 to 0.5 g/L (Ong et al., 2013). Calcium chloride concentrations up to 0.1 g/L (1%) did not affect Lp_1760 activity (Figure 4C). The activity showed by Lp_1760 suggests that this esterase could play a role in modulating flavor profile during cheese ripening.

The obtained results indicated that Lp_1760 is a tributyrin esterase that retains activity under conditions commonly found during cheese making and ripening, such as cold temperature, acidic pH, and the presence of salt, lactic acid, or calcium chloride. Another advantage for the potential use of Lp_1760 in cheese making is its thermostability. Further assays need to be done under combined conditions to further evaluate the effect of the simultaneous presence of different factors on Lp_1760 activity.

CONCLUSIONS

In the present study, the tributyrin esterase Lp_1760 from L. plantarum, an important nonstarter LAB species which can be found during cheese ripening, was purified and biochemically characterized. Lp_1760 tributyrin esterase may contribute positively to cheese flavor development, as it shows marked activity on tributyrin and on p-nitrophenyl esters of FA. Lp_1760 exhibits high activity at the conditions (temperature and pH) and in the presence of compounds (salt, lactic acid, or calcium chloride) found during cheese making and ripening. Based on the findings reported in our study, a tributyrin esterase or lipase of such characteristics may play a relevant role in flavor development during ripening, either produced in situ or added to milk or curd cheese manufacture.
