ABSTRACT

Cheddar-type cheese was fortified with the antioxidant *Inula britannica* flower extract (IBE). Cheddar-type cheeses manufactured with varying concentrations of IBE (0, 0.25, 0.5, 0.75, and 1% wt/vol) were analyzed during storage at 4°C, 0, 1, 2, and 3 wk after production. Higher IBE concentrations resulted in higher protein and ash contents, with a concomitant decrease in pH, total solid, and fat content relative to the unfortified control cheese. The total phenolic content also increased with IBE concentration, but decreased over longer storage periods. The antioxidant activities of the cheeses, determined as 2,2-diphenyl-1-picrylhydrazyl (DPPH) free-radical scavenging activity and ferric thiocyanate assay results, increased proportionally to the total phenolic content. The highest antioxidant effect was observed in the 1% IBE-fortified cheese, showing 79 and 86% antioxidant effects in the DPPH and ferric thiocyanate assays, respectively. At the 1-wk time point, the 5 cheese preparations underwent sensory evaluation for odor, taste, texture, color, and overall quality, determined using a descriptive analysis by a trained panel (n = 20). The addition of IBE resulted in some increases in extract odor and taste. Overall, IBE showed good potential as an antioxidant supplement for dairy products. Key words: *Inula britannica*, Cheddar-type cheese, physicochemical property, antioxidant activity

Short Communication

The flower of *Inula britannica* has been used as a traditional herbal medicine for the treatment of digestive disorders, inflammation, and bronchitis (Bai et al., 2005), and its use is approved by the Korea Food and Drug Administration (Lee et al., 2013). The antioxidant activities of the *I. britannica* flower are mainly attributed to its phenolic content, which is reported to consist mainly of luteolin, diosmetin, chrysoeriol, kaempferol, quercetin, 6-hydroxyluteolin-6-methyl ether, spinacetin, and eupatin (Chung et al., 1999; Park et al., 2000; Bai et al., 2005). The *I. britannica* flower has mainly been used in medicinals, cosmetics, beverages, and natural preservatives (Seo et al., 2002; Kim et al., 2011). However, *I. britannica* flower has not been used in dairy products.

Cheese is a solid milk concentrate that consists mainly of proteins. During the cheese making process, curd is generally made via the enzymatic coagulation of milk casein (Robitaille et al., 2004). Cheddar-type cheese, especially young Cheddar-type cheese, has been analyzed with respect to texture, performance, and flavor, in a study that focused on functional properties (Hassan et al., 2007). In South Korea, mozzarella is the most popular cheese type with a 60% value share in 2012, followed by Cheddar with a 23% value share (Kansendossier Zuid, 2013). The reported antioxidant activity of cheese is derived from the milk peptides released from casein by lactic acid bacteria (Gupta et al., 2009). Histidine and proline are known to have a lipoprotein-peroxidation inhibitory effect, whereas tyrosine and tryptophan have shown scavenging capability for the 2,2-azinobis (3-ethylbenzothiazoline)-6-sulfonic acid (ABTS+) radical.

Phenolic compounds have been proposed for use as nutritional ingredients to improve the functional properties of milk and dairy products. Green tea extract (Giroux et al., 2013), red ginseng extract (Jung et al., 2015), catechin (Rashidinejad et al., 2015), grape extract (Han et al., 2011a; da Silva et al., 2015), and dehydrated cranberry powder (Han et al., 2011a) have all been used as enrichment ingredients for their antioxidant effects. Although cheese contains small amounts of phenolic compounds, their effect is limited due to their low antioxidant activity (Han et al., 2011b).
is because the interaction of phenolic compounds and proteins can be limited by the pH, molar ratio, and molecular properties of the polyphenols (Gad and El-Salam, 2010).

Cheddar-type cheese is usually ripened for 3 mo, but low-priced young cheese is popular in Quebec, Canada (St-Gelais et al., 2009). Cheddar-type cheese enriched with green tea extract has been studied over a 29-d storage period (Giroux et al., 2013). The objective of the present study was to produce Cheddar-type cheeses fortified with *I. britannica* flower extracts (IBE) and evaluate their physicochemical properties, antioxidant activities, and sensory characteristics. In addition, the effect of storage time on the antioxidant effect was investigated over 3 wk at 4°C.

*Inula britannica* flowers were purchased from traditional medicinal markets in Seoul, Korea, and commercially available milk was used (Seoul Dairy Co., Seoul, Korea). Liquid rennet (Naturen) was obtained in Seoul, Korea, and commercial starter culture (ABT-L) was purchased from Chr. Hansen, Hørsholm, Denmark. The starter culture was incubated at 37°C to allow for coagulation. After a 15-min incubation, the absorbance at 517 nm was measured using a spectrophotometer (Optizen 2120 UV; Mecasys Co., Ltd., Daejeon, Korea). The total phenolic content was calculated on a standard curve constructed using gallic acid (0–250 mg/L; Sigma-Aldrich), and was expressed as milligrams of gallic acid equivalents per gram (mg of GAE/g).

The DPPH radical-scavenging activity of the cheeses was determined using the method of Savikin et al. (2009). Two hundred microliters of 10% cheese sample solution was mixed with 1 mL of 100 μM DPPH solution. After a 15-min incubation, the absorbance at 517 nm was measured using a spectrophotometer. Butylated hydroxytoluene at 1 mg/mL concentration was used as a positive control. The DPPH radical-scavenging activity was calculated from the following formula:

\[
\text{DPPH radical-scavenging activity} (%) = \frac{1 - (\text{sample absorbance at 517 nm/control absorbance at 517 nm})}{1} \times 100.
\]

The antioxidant activity of the Cheddar-type cheeses was measured by FTC using a procedure modified from Lee et al. (2004). Aliquots of 10% solutions of each cheese type were subjected to analysis. Vitamin C at 1 mg/mL concentration was used as a positive control. The reaction mixture, comprising 100 μL of sample, 0.2 mL of linoleic acid solution (25 mg/mL) in ethanol, 0.4 mL of 40 mM phosphate buffer, and 0.2 mL of distilled water, was incubated at 37°C in the dark for 72 h. Thereafter, 0.1-mL aliquots were diluted with 4 mL of 70% ethanol and 0.1 mL of 30% ammonium thiocyanate was added. This was followed by the addition of

20 mM FeCl₂ in 3.5% HCl. The absorbance of the red color was measured at 500 nm against a blank that used water instead of sample. Antioxidant activity was calculated from the following formula:

\[
\text{antioxidant activity (\%)} = \left[1 - \frac{\text{sample absorbance at 500 nm/blank absorbance at 500 nm}}{}\right] \times 100.
\]

Sensory evaluation of fresh Cheddar-type cheeses was performed by a panel of 20 trained assessors (10 males and 10 females) recruited and screened according to accepted international standards (ISO/DIS 13299:1998; ISO, 1998). The cheeses were cut into 2 cm × 2 cm blocks, and each sample was labeled with a random 5-digit number and served at room temperature. Assessment scales for 10 attributes were displayed for scoring, and were anchored by verbal descriptors at each end, with the left side of the scale corresponding to the lowest intensity, extremely unlike, or absence (value 1) of the attribute, and the right side corresponding to the highest intensity, extremely like, or perfect condition (value 10) of the attribute.

The results of this study are expressed as the mean ± standard deviation of the treatments carried out in triplicate, and were analyzed by one-way ANOVA, Duncan’s multiple range test, and Pearson correlation. The probability level for statistical significance was set at \( P < 0.05 \). The SPSS version 18 software (Chicago, IL) was used for all analyses.

The compositions of the IBE-fortified cheddar-type cheeses are presented in Table 1. The addition of IBE did not have a significant effect on TS or fat (\( P > 0.05 \)). However, the protein content, ash content, and pH were significantly affected (\( P < 0.05 \)). The control cheese contained 37.77% total solids, 23.72% protein, 22.02% fat, and 0.76% ash, and had a pH of 5.1. Among IBE-fortified cheeses, the total solids, fat contents, and pH decreased with an increase in IBE content, whereas the protein and ash contents increased. The IBE itself contained 91.47% total solids, 6.55% protein, 3.26% fat, and 17.65% ash. The correlation coefficients between protein and addition of IBE, and between ash and addition of IBE were 0.569 (\( P < 0.05 \)) and 0.844 (\( P < 0.01 \)), respectively. This might be due to the addition of IBE having affected the water-holding capacity of the cheese. The IBE seemed to promote the contraction of the cheese matrix and the expulsion of whey, reducing the quantity of entrapped water in the protein network. In agreement with this, phenolic compounds have been found to decrease the curd moisture content (Han et al., 2011a). Moreover, the protein recovery in cheese was consistent with the results obtained using green tea extract (Giroux et al., 2013) and grape extract (da Silva et al., 2015). The increase in protein was likely due to interactions between the polyphenolic compounds and milk protein, resulting in cross-linking or precipitation (O’Connell and Fox, 2001).

Phenolic compounds are important plant constituents because of their antioxidant effect. The total phenolic contents of the IBE-fortified cheeses were calculated using the gallic acid standard equation, and the data are presented in Figure 1A. The total phenolic content of 0.1 IBE in water was 82.95 mg of GAE/g. At 0 wk of storage, the total phenolic contents of cheese fortified with 0, 0.25, 0.5, 0.75, and 1% IBE were 44.43, 54.79, 58.75, 59.52, and 70.82 mg of GAE/g, respectively, indicating that the total phenolic contents increased with the addition of IBE (\( r = 0.680, P < 0.01 \)). However, the total phenolic contents decreased with longer storage periods (\( r = -0.703, P < 0.01 \)), where the reduction was greater for the cheese fortified with 1% IBE than with 0.1% IBE in water. This decrease was due to the increased interaction between phenolic compounds and proteins (Gad and El-Salam, 2010).

The dietary intake of natural antioxidants is correlated with decreased risks for various diseases such as inflammation, cancer, and cardiovascular diseases (Yoon et al., 2015). The antioxidant activity was assessed here using 2 methods, owing to diversity in the antioxidant mechanisms. The radical-scavenging effect and the lipid-peroxidation inhibitory effect were dem-

\(^1\)Control = Cheddar-type cheese made from unfortified milk; A = Cheddar-type cheese made from 0.25% IBE-fortified milk; B = Cheddar-type cheese made from 0.5% IBE-fortified milk; C = Cheddar-type cheese made from 0.75% IBE-fortified milk; D = Cheddar-type cheese made from 1% IBE-fortified milk.
Lee et al.

onstrated using the DPPH radical-scavenging assay and the FTC assay, respectively.

The DPPH radical-scavenging assay shows the hydrogen-donating activity of the fortified cheese (Figure 1B). Increasing the concentration of IBE resulted in increased DPPH radical-scavenging activity (r = 0.773, P < 0.01). At 0 wk of storage, the DPPH radical-scavenging activities of the cheeses fortified with 0, 0.25, 0.5, 0.75, and 1% IBE were 47.76, 53.34, 56.32, 68.81, and 79.07%, respectively. However, the DPPH radical-scavenging activity decreased with longer storage periods (r = −0.559, P < 0.05). In addition, the correlation coefficient between total phenolic content and DPPH radical-scavenging activity was 0.927 (P < 0.01).

The antioxidant activities of the Cheddar-type cheeses determined with the FTC assay are shown in Figure 1C. This assay demonstrates the reducing power and metal-chelating capability of the fortified cheese. The IBE-fortified cheeses had a higher antioxidant activity than control cheese (r = 0.960, P < 0.01). At 0 wk of storage, the antioxidant activities of cheeses fortified with 0, 0.25, 0.5, 0.75, and 1% IBE were 24.21, 29.05, 54.57, 66.34, and 86.74%, respectively. In particular, 0.75 and 1% IBE showed noticeable antioxidant effects compared with the control cheese. Because the FTC value is based on reduction of ferric ion, the Cheddar-type cheese fortified with IBE was obviously capable of donating a single electron or hydrogen atom for the reduction reaction. The antioxidant effect evaluated by the FTC assay also decreased with longer storage periods (r = −0.105, P < 0.01). In addition, the correlation coefficient between the total phenolic contents and FTC values was 0.713 (P < 0.01).

The results of the antioxidant activity decreased with increasing storage period and correlated with a decrease in total phenolic content indicate that the decreases were related to the fermentation or ripening process (Yoon et al., 2015). Nevertheless, the IBE-fortified Cheddar-type cheeses were demonstrated to have free-radical-scavenging, lipid peroxidation-inhibiting, and ferric-ion-reducing powers. Although longer storage of the cheeses could negatively affect their antioxidant activities, the antioxidant effects remained for up to 3 wk, especially those of lipid peroxidation inhibition and ferric in reduction.

The flavor, taste, texture, and color profiles of the samples were determined using a descriptive analysis by a trained sensory evaluation panel. The addition of IBE increased the extract-taste, bitterness, and extract-odor ratings, but did not have noticeable effects on extract odor and acid taste (Table 2). However, the addition of IBE did lower the milk-odor and milk-taste ratings. In addition, the sensory values for extract odor, acid taste, bitterness, and dark color were higher than for

Figure 1. Antioxidant activity in Cheddar-type cheeses fortified with Inula britannica flower extract (IBE). (A) Total phenolic contents, (B) 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical-scavenging activity, and (C) antioxidant activity by the ferric thiocyanate method. Control, Cheddar-type cheese made from unfortified milk; butylated hydroxytoluene (BHT) or vitamin C, positive control; A, Cheddar-type cheese made from 0.25% IBE-fortified milk; B, Cheddar-type cheese made from 0.5% IBE-fortified milk; C, Cheddar-type cheese made from 0.75% IBE-fortified milk; D, Cheddar-type cheese made from 1% IBE-fortified milk; white, 0 wk; light gray, 1 wk; dark gray, 2 wk; black, 3 wk. GAE = gallic acid equivalents.
Therefore, these results showed that supplementation with IBE has good potential for use in dairy products for enhancing antioxidant effects.
