**ABSTRACT**

Yogurt is a healthy dairy food fermented by lactic acid bacteria (LAB). Because consumers demand healthier and more nutritious yogurt, numerous substances have been used to supplement yogurt. Chia seed has been reported to contain abundant phenolic compounds, dietary fiber, and n-3 fatty acids and therefore is a potential functional food additive. The aim of this study was to investigate the influence of chia seed extracts on the physicochemical and bioactive properties of set-type yogurt. Yogurt was fortified with chia seed water extract (CSWE) or chia seed ethanol extract (CSEE) at 0.05 or 0.1% (vol/vol). Results showed that supplementation with CSWE or CSEE significantly accelerated the fermentation rate and growth of LAB. Both CSWE and CSEE improved the viscosity, syneresis, and water-holding capacity of yogurt. The radical scavenging activity of yogurt was increased with both extracts, and the 0.1% CSEE yogurt exhibited the highest radical scavenging activity. Furthermore, 0.1% CSEE yogurt significantly inhibited lipopolysaccharide-induced production of hydrogen peroxide in human colon cells. Addition of chia seed extract improves the growth of LAB, the physiochemical properties, and the health-beneficial effects of set-type yogurt.

**Key words:** yogurt, chia seed, lactic acid bacteria, functional foods

Recent consumer trends have shown that consumption of healthful food supports healthy lifestyles and reduces the risk of disease (Asioli et al., 2017). These changes in consumer demand have driven the food industry to develop functional foods with health-beneficial effects (Vecchio et al., 2016). Thus, yogurt per se is not usually considered a rich source of bioactive ingredients (Ozturkoglu-Budak et al., 2016). The development of more nutritious yogurt is an ongoing topic in dairy science.

Chia (*Salvia hispanica* L.) is native to a region from western Mexico extending to northern Guatemala and has been consumed for about 5,500 years (Ullah et al., 2016). Chia seed contains a high amount of dietary fiber and antioxidants derived from phenolic compounds and PUFA (Sargi et al., 2013). Previous studies have shown that chia seed exhibits various beneficial health effects because of its antioxidant, anti-inflammatory, and cardioprotective activities (Ullah et al., 2016). Because of these health effects, chia seed is a potential bioactive ingredient for use in functional foods. In fact, chia seed has been used to manufacture bread, frankfurters, and yogurt (Coelho and de las Mercedes Salas-Mellado, 2015; Pop et al., 2015; Pintado et al., 2016). In yogurt manufacture, supplementation with 1.4% chia seeds improved the viability of probiotic bacteria during 21 d of shelf life (Pop et al., 2015). However, no study has yet evaluated the effects of chia seed on physicochemical and antioxidant properties of yogurt. Therefore, the aim of this study was to characterize (1) fermentation and physicochemical properties, and (2) bioactive features of chia seed-supplemented yogurt.

Chia seed (Organica Inc., Seoul, Korea) was ground to prepare chia seed extracts (CSE). Chia seed water extract (CSWE) was prepared by heating chia seed in distilled water (5% wt/vol) at 95°C for 1 h. Chia seed ethanol extract (CSEE) was prepared by adding chia seed to 70% ethanol (5% wt/vol) with stirring for 24 h, at room temperature. The filtered extracts were concentrated with a rotary vacuum evaporator (Tokyo Rikakikai Co. Ltd., Tokyo, Japan). The residue was freeze-dried and stored in deep freezer at −80°C until further use. To prepare yogurts, CSWE and CSEE (0.05

**Short Communication**

Yogurt is a well-known dairy food produced by fermentation of milk with lactic acid bacteria (LAB). Because bioactive peptides are produced by LAB during yogurt fermentation, yogurt has higher biological activity than milk (Pessione and Cirrincione, 2016). Specifically, some peptides in yogurt have antioxidant activities such as inhibition of lipid peroxidation and radical removal (Sah et al., 2014; Nielsen et al., 2017).
and 0.1%, wt/wt) were added to 12% nonfat milk. The mixture was pasteurized at 85°C for 30 min and cooled to 42°C. The LAB starter included a mixture of Lactobacillus acidophilus (35%), Streptococcus thermophilus (35%), and Bifidobacterium longum (30%; Samik Dairy and Food Co. Ltd., Seoul, Korea). The starter culture was prepared by adding 0.34 g of LAB starter culture powder to 100 mL of 12% nonfat milk. Yogurts were inoculated with 3.5% yogurt starter culture (vol/vol). Yogurt was incubated at 42°C until the pH reached 4.6. During the fermentation period, LAB were enumerated using the spread plate method by sequentially diluting with peptone water to the desired dilution factor on selective agar medium. Lactobacillus acidophilus was cultured on MRS-LP agar supplemented with 0.3% lithium chloride, 0.05% l-cysteine hydrochloride (0.1 g/mL; Oxoid, Basingstoke, UK). Bifidobacterium longum was cultured on M17 agar (Oxoid) supplemented with 0.5% lactose (Samchun, Seoul, Korea). Bifidobacterium longum was cultured on MRS-LP agar supplemented with 0.3% lithium chloride, 0.05% l-cysteine hydrochloride (0.1 g/mL), and 0.9% sodium propionate (Sigma-Aldrich, St, Louis, MO). Each strain was incubated at 37°C for 48 h under aerobic (L. acidophilus and S. thermophilus) or anaerobic (B. longum) conditions. Acidification kinetics were estimated as described previously (Oh et al., 2016). The maximum acidification rate ($V_{\text{max}}$) was calculated based on the variation in pH over time (dpH/dt), expressed in pH units × 10−3/min. At the end of fermentation, the following kinetic parameters were calculated: time taken to reach $V_{\text{max}}$ ($t_{\text{max}}$; h); time taken to reach pH 5.0 ($t_{\text{pH}5.0}$; h); and time taken to complete fermentation ($t_f$; h). The pH of all yogurt samples was determined using a pH meter (Mettler-Toledo, Columbus, OH).

Syneresis and water-holding capacity (WHC) were determined as described previously (Amaya-Llano et al., 2008; Ünal and Akalin, 2013). Ten grams of yogurt sample was centrifuged at 500 × g for 5 min and the supernatant was poured off and weighed. Viscosity was measured using a DV-E Viscometer (Brookfield, Toronto, ON, Canada). Next, 35 g of sample was transferred to a 50-mL conical tube and measured after 5 min of immersion at 50 rpm using a viscometer 63 spindle, and measured at 1-min intervals up to 8 min. The color parameters lightness ($L^*$), red-green color ($a^*$), and yellow-blue color ($b^*$) of yogurts were measured using a colorimeter (Konica Minolta Inc., Tokyo, Japan). Radical scavenging activity was tested using 2,2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2′-azinoobis (3-ethylbenzothiazoline-6-sulphonic acid) (ABTS) as described previously (Zhang et al., 2019). Total phenolic compounds (TPC) were estimated as described previously, with minor modifications (Kabir et al., 2015). Briefly, a yogurt extract (30 μL) diluted with 120 μL of distilled water was blended with 30 μL of Folin-Ciocalteu reagent and 30 μL of sodium carbonate in a 96-well plate. The plate was incubated at room temperature for 30 min in the dark. The absorbance of the sample was measured at 595 nm.

Human colon cells (HT-29) were cultured in RPMI-1640 medium supplemented with 10% fetal bovine serum and 1% penicillin-streptomycin. To measure the intracellular production of reactive oxygen species (ROS), cells were grown to approximately 80% confluency in a 6-well plate. Cells were pretreated with yogurt extracts for 15 h, followed by treatment with LPS (1 μg/mL, 24 h) to induce production of ROS. The cells were incubated with 2′,7′-dichlorofluorescin diacetate (DCF-DA; 10 μM, 30 min). Fluorescence intensity was detected using a fluorescent microscope (Eclipse Ti2-U, Nikon Co. Ltd., Tokyo, Japan).

Data were expressed as means ± standard errors of the mean. Statistical significance was confirmed with SPSS-PASW statistics software for Windows (version 18.0; SPSS, Chicago, IL) by one-way ANOVA and Tukey’s post hoc test. P-values < 0.05 were considered to indicate a statistically significant difference.

The results showed that the pH of CSE-supplemented yogurts (i.e., containing CSWE and CSEE) was markedly lower during fermentation than that of control yogurt without added extracts (Figure 1A). In terms of acidification, supplementation of CSE significantly reduced the fermentation time of yogurt (Figure 1B). Addition of 0.1% CSWE and CSEE showed a 1.6-fold increase in $V_{\text{max}}$ and a decrease in $t_{\text{max}}$. In addition, both $t_{\text{pH}5.0}$ and $t_f$ were decreased by CSE supplementation. Plant or seed extracts have positive effects on yogurt fermentation. Yogurt supplemented with 3% amaranth seed and red ginseng extract resulted in a rapid decrease in pH compared with control yogurt (Dimitrova and Kartalska, 2015; Jung et al., 2016). Addition of green tea also reduced fermentation time in a set-type yogurt (Jeong et al., 2018), probably because specific active ingredients derived from the plant or seeds played a prebiotic role and promoted growth of LAB.

In particular, the addition of CSE enhanced L. acidophilus counts at the end of fermentation (6
The growth of LAB may be promoted by prebiotic components (Pandey et al., 2015). Chia seed is reported to be rich in polyphenolic compounds, mainly chlorogenic acid (7.1 × 10^{-3} mol/kg), caffeic acid (6.6 × 10^{-3} mol/kg), and myricetin (3.1 × 10^{-3} mol/kg) (Muñoz et al., 2013; Pellegrini et al., 2018). A study showed that polyphenols and phenolic extracts derived from plants and seeds increase the growth of colonic bacteria (Peluso et al., 2014). In detail, chlorogenic acid and caffeic acid derived from plant leaf extracts can increase the viability of LAB during yogurt fermentation (Oh et al., 2016). The addition of chlorogenic acid to a batch culture vessel significantly increased the viability of Bifidobacterium spp. (Santana-Gálvez et al., 2017). In contrast, myricetin can be hydrolyzed to glucose or galactose, which provides energy to bacteria (Li et al., 2016). In fact, most dietary polyphenols (90–95%) reach the colon, where polyphenol metabolism is mediated by colonic bacteria (i.e., Lactobacillus spp. and Bifidobacterium spp.; Cardona et al., 2013). Our data support the role of polyphenols in the growth of LAB: the TPC in CSE-added yogurts were significantly increased in a dose-dependent manner (Figure 2A). These data suggest that polyphenols in CSE increased the viable counts of L. acidophilus, S. thermophilus, and B. longum.

The characteristics of chia seed yogurts are listed in Table 1. The color of yogurt is one of the crucial sensory characteristics (García-Pérez et al., 2005). Addition of CSWE decreased the brightness (L*) of yogurt, whereas CSEE increased the redness (a*) of yogurt. In addition, supplementation of both CSE decreased yellowness (b*). The viscosity of 0.1% CSWE and 0.1% CSEE yogurts increased significantly, by 14.78 and 21.32%, respectively, compared with that of control yogurt (P < 0.05). Similarly, the addition of polyphenols derived from blackcurrants increased the viscosity compared with control yogurt (Sun-Waterhouse et al., 2013). Syneresis is the extraction of liquid from the yogurt gel matrix and it leads to the separation of whey. Water-holding capacity is the amount of water possessed by the hydrated sample following application of an external force. Both syneresis and WHC are important physical characteristics of yogurt by increasing the polyphenol content and stabilizing the gel matrix in yogurt.

To evaluate the antioxidant effects of CSE yogurt, we evaluated the levels of TPC and antioxidant activity in CSE yogurts (Figure 2). The TPC was increased by a dose-dependent addition of CSWE or CSEE in yogurt (Figure 2A). The 0.1% CSWE and 0.1% CSEE treatments increased TPC by 15.9% [57.00 µg of gallic acid equivalents (GAE)/mL] and 30.6% (64.20 µg of GAE/mL), respectively, compared with control yogurt (49.2 µg of GAE/mL). The antioxidant activities of CSWE and CSEE were measured using a radical scavenging assay (Figure 2B and C). Radical scavenging activity of both DPPH and ABTS increased by 24.3% (0.1% CSEE) and 15.1% (0.1% CSEE), respectively (both P < 0.05), compared with controls. We also evaluated the antioxidant effect of CSE yogurt in human colon cancer epithelial cells. Generation of intracellular ROS was detected using the fluorescent dye DCF-DA (Figure 2D). Treatment of cells with LPS significantly increased the level of ROS compared with control (P < 0.05). However, pretreatment with yogurts containing 0.1% CSWE and 0.1% CSEE decreased LPS-induced ROS production. Antioxidant properties of CSE yogurt as shown by TPC and radical scavenging activity are likely responsible for the lower ROS production observed in cells. Control yogurt without CSE also decreased cellular ROS generation. These findings are consistent with the results of assays where yogurt with and without CSE showed strong radical scavenging activity (Figure 2B and C). Excessive generation of ROS in the gastrointestinal tract causes oxidative stress, resulting in diseases such as inflammatory bowel disease (IBD; Bhattacharyya et al., 2014). Chia seed contains abundant polyphenols and PUFA with antioxidant activity because of the presence of components such as α-linolenic acid, chlorogenic acid, and caffeic

Oxidative components (Pandey et al., 2015). Chia seed is reported to be rich in polyphenolic compounds, mainly chlorogenic acid (7.1 × 10^{-3} mol/kg), caffeic acid (6.6 × 10^{-3} mol/kg), and myricetin (3.1 × 10^{-3} mol/kg) (Muñoz et al., 2013; Pellegrini et al., 2018). A study showed that polyphenols and phenolic extracts derived from plants and seeds increase the growth of colonic bacteria (Peluso et al., 2014). In detail, chlorogenic acid and caffeic acid derived from plant leaf extracts can increase the viability of LAB during yogurt fermentation (Oh et al., 2016). The addition of chlorogenic acid to a batch culture vessel significantly increased the viability of Bifidobacterium spp. (Santana-Gálvez et al., 2017). In contrast, myricetin can be hydrolyzed to glucose or galactose, which provides energy to bacteria (Li et al., 2016). In fact, most dietary polyphenols (90–95%) reach the colon, where polyphenol metabolism is mediated by colonic bacteria (i.e., Lactobacillus spp. and Bifidobacterium spp.; Cardona et al., 2013). Our data support the role of polyphenols in the growth of LAB: the TPC in CSE-added yogurts were significantly increased in a dose-dependent manner (Figure 2A). These data suggest that polyphenols in CSE increased the viable counts of L. acidophilus, S. thermophilus, and B. longum.

The characteristics of chia seed yogurts are listed in Table 1. The color of yogurt is one of the crucial sensory characteristics (García-Pérez et al., 2005). Addition of CSWE decreased the brightness (L*) of yogurt, whereas CSEE increased the redness (a*) of yogurt. In addition, supplementation of both CSE decreased yellowness (b*). The viscosity of 0.1% CSWE and 0.1% CSEE yogurts increased significantly, by 14.78 and 21.32%, respectively, compared with that of control yogurt (P < 0.05). Similarly, the addition of polyphenols derived from blackcurrants increased the viscosity compared with control yogurt (Sun-Waterhouse et al., 2013). Syneresis is the extraction of liquid from the yogurt gel matrix and it leads to the separation of whey. Water-holding capacity is the amount of water possessed by the hydrated sample following application of an external force. Both syneresis and WHC are important physical characteristics of yogurt by increasing the polyphenol content and stabilizing the gel matrix in yogurt.

To evaluate the antioxidant effects of CSE yogurt, we evaluated the levels of TPC and antioxidant activity in CSE yogurts (Figure 2). The TPC was increased by a dose-dependent addition of CSWE or CSEE in yogurt (Figure 2A). The 0.1% CSWE and 0.1% CSEE treatments increased TPC by 15.9% [57.00 µg of gallic acid equivalents (GAE)/mL] and 30.6% (64.20 µg of GAE/mL), respectively, compared with control yogurt (49.2 µg of GAE/mL). The antioxidant activities of CSWE and CSEE were measured using a radical scavenging assay (Figure 2B and C). Radical scavenging activity of both DPPH and ABTS increased by 24.3% (0.1% CSEE) and 15.1% (0.1% CSEE), respectively (both P < 0.05), compared with controls. We also evaluated the antioxidant effect of CSE yogurt in human colon cancer epithelial cells. Generation of intracellular ROS was detected using the fluorescent dye DCF-DA (Figure 2D). Treatment of cells with LPS significantly increased the level of ROS compared with control (P < 0.05). However, pretreatment with yogurts containing 0.1% CSWE and 0.1% CSEE decreased LPS-induced ROS production. Antioxidant properties of CSE yogurt as shown by TPC and radical scavenging activity are likely responsible for the lower ROS production observed in cells. Control yogurt without CSE also decreased cellular ROS generation. These findings are consistent with the results of assays where yogurt with and without CSE showed strong radical scavenging activity (Figure 2B and C). Excessive generation of ROS in the gastrointestinal tract causes oxidative stress, resulting in diseases such as inflammatory bowel disease (IBD; Bhattacharyya et al., 2014). Chia seed contains abundant polyphenols and PUFA with antioxidant activity because of the presence of components such as α-linolenic acid, chlorogenic acid, and caffeic
Figure 1. Changes in pH (A), acidification kinetic parameters (B), and viable counts (log cfu/mL) of lactic acid bacteria (Lactobacillus acidophilus, Streptococcus thermophilus, and Bifidobacterium longum) in yogurt-supplemented chia seed extract (CSE) during fermentation (C, D, E). Control = without addition of CSE (black); 0.05% and 0.1% CSWE = 0.05% and 0.1% chia seed water extract added to yogurt (blue); 0.05 and 0.1% CSEE = 0.05 and 0.1% chia seed ethanol extract added to yogurt (red). $V_{\text{max}}$ = acidification rate; $t_{\text{max}}$ = time at which $V_{\text{max}}$ was reached; $t_{\text{pH 5.0}}$ = time to reach pH 5.0; and $t_{f}$ = time to complete the fermentation. Results represent the mean ± SEM, with $n = 3$. Bars with different letters (a–d) indicate significant differences ($P < 0.05$) within each kinetic parameter.
These chia seed components show strong antioxidant and anti-inflammatory effects that can provide additional bioactive properties to yogurt. In a clinical study, ingestion of milled chia seed at 25 g/d increased α-linolenic acid content by 38% in the serum of postmenopausal women (Jin et al., 2012). Data from past studies also demonstrate that α-linolenic acid
inhibits inflammation by decreasing inflammatory mediators (e.g., IL-6, IL-8, cyclooxygenase-2, and tumor necrosis factor-α) in human colon epithelial cells and IBD-induced rats (Reifen et al., 2015). The antioxidant effects of chia seed contributed to a decrease in DNA strand scission induced by hydroxyl and peroxyl radicals and increased the plasma antioxidant enzymes (da Silva Marineli et al., 2015; Rahman et al., 2017). Another major chia seed component, chlorogenic acid, and its metabolite caffeic acid attenuated dextran sulfate sodium-induced colitis in mice, and decreased IL-8 in human colon epithelial cells (Shin et al., 2015). Furthermore, chlorogenic acid decreased intestinal ROS and inflammation in rats (Zhou et al., 2016). Because oxidative stress and inflammation are major contributors (e.g., IL-6, IL-8, cyclooxygenase-2, and tumor necrosis factor-α) in human colon epithelial cells and IBD-induced rats (Reifen et al., 2015). The antioxidant effects of chia seed contributed to a decrease in DNA strand scission induced by hydroxyl and peroxyl radicals and increased the plasma antioxidant enzymes (da Silva Marineli et al., 2015; Rahman et al., 2017). Another major chia seed component, chlorogenic acid, and its metabolite caffeic acid attenuated dextran sulfate sodium-induced colitis in mice, and decreased IL-8 in human colon epithelial cells (Shin et al., 2015). Furthermore, chlorogenic acid decreased intestinal ROS and inflammation in rats (Zhou et al., 2016). Because oxidative stress and inflammation are major contributors to the initiation and development of IBD, our data suggest that ingestion of CSE-supplemented yogurt may protect against such intestinal disease. Taken together, our data indicate that yogurt supplemented with CSE enhances antioxidant activity in colon epithelial cells due to bioactive components in chia seed and that the ingestion of CSE-supplemented yogurt can improve colon health.

In conclusion, supplementation of yogurt with chia seed extract shortened the fermentation time and increased LAB counts. Furthermore, the physicochemical properties (i.e., viscosity, syneresis, WHC, and color) and antioxidant effects of cells were significantly improved in yogurt supplemented with chia seed extracts. This work highlights the enhanced quality characteristics and beneficial effects of CSE-supplemented yogurt on colon health.
