Calf health monitoring in Norwegian dairy herds. By Gulliksen et al., page 1660. Accurate recordings of calf health are a valuable and necessary tool for herd health, genetic improvement, and for research purposes. A survey on calf health including 135 Norwegian dairy herds was conducted from 2004 through 2006. Disease recordings were made on 6,668 calves born during the project period using the Norwegian Cattle Health Recording System. More than 75% of the recordings were due to diarrhea and respiratory disease. Different methods for validation of health data indicated varying degrees of underestimation of calf health records using this system.
